Since QoL is subjectively evaluated through questionnaires (14), further studies would be necessary to follow the evolution of QoL over time, in these patients, which we intend to do in the near future.

CONCLUSIONS

The QoL in pediatric patients admitted in ICU with various types of trauma did not differ significantly between age groups, sexes or residential environments. The global SF-12 score revealed a decrease in the QoL, generated by the very intense bodily pains that significantly affected the patients' physical and emotional health.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding.

EFFECTS OF EXOSOMES DERIVED FROM MSC-iPSC ON FIBROBLASTS *IN VITRO* IN THE PRESENCE OF PLATELET-RICH PLASMA (Abstract): Mesenchymal stem cells, as well as mesenchymal stem cells-induced pluripotent stem cells, can definitely induce alterations of fibroblasts and osteoblasts micro medium, stimulating the development of bone around the dental implants. **Aim**: The purpose of the current study was represented by the following of the effects of stimulation and inhibition of multiple intracellular functional pathways of senescent gingival fibroblasts in culture when exosomes released from pluripotent stem cells reprogrammed from mesenchymal stem cells and platelet-rich plasma were used. Materials and m**ethods**: We used flow cytometry to measure the production of the beta-galactosidase level by gingival fibroblasts in culture after 30 passages and ultraviolet treatment. **Results**: Reduction of β-galactosidase concentrations in senescent gingival fibroblasts was evident upon administration of platelet-rich plasma, exosomes and exosomes co-administered the same time with: LY-294002, nutlin-3, berberine, resveratrol, collagen, thrombin, and fibronectin. On the other side, lipopolysaccharide (which might induce a pro-inflammatory profile on iPSC-MSC) enhanced the production of β-galactosidase. The most intense effects were associated with collagen, thrombin, fibronectin, resveratrol, and berberine. **Conclusions**: Exosomes isolated from pluripotent stem cells derived from mesenchymal stem cells, administered in the culture medium of senescent gingival fibroblasts, can modify the degree and evolution of the senescence of these last cells by potentiating, activating, or stimulating some intracellular pathways of biological signal transduction. **Keywords:** MSC, MSC-iPSC, GINGIVAL FIBROBLASTS, EXOSOMES, LY294002, NUTLIN-3, BERBERINE RESVERATROL, LPS, COLLAGEN, THROMBIN, FIBRINOGEN, PLATELET-RICH PLASMA.

INTRODUCTION

Large vertical and horizontal alveolar ridge deficits in mandibular and maxillary bone remain a barrier for doctors practicing implant dentistry. One of the disadvantages of porous blocks for bone repair in big lesions in the oral cavity and in the musculoskeletal system is that the fibrin clot does not adequately cover the interior pores and, the same time, does not persist long enough

to accommodate cell migration into the center of the block (1).

Platelet concentrates, namely platelet-rich plasma, fibrin, or concentrated growth factors, represent cost-effective autologous preparations comprising platelet-derived growth factor, transforming growth factor β, insulin-like growth factor 1, as well as vascular endothelial growth factor. As a result, they are commonly employed in regenerative medicine to repair wounds, nerve damage, cartilage, and bone abnormalities. Unfortunately, following administration, these preparations rapidly release growth factors, which quickly lose their effectiveness. As a result, the therapy must be repeated, which causes the patient more pain and anguish. Recent studies indicate that mixing platelet concentrates with biomaterials solves this problem by releasing growth factors in a more sustainable manner. Furthermore, this notion fits with the most recent advancements in tissue engineering, including biomaterials, bioactive agents, and cells (2).

The progress made in tissue engineering is the result of a thorough investigation of cell-tissue interactions. The selection of a specific biomaterial in Tissue Engineering is crucial because it serves as an interface for adherent cells in the establishment of a microenvironment suited for cell proliferation and differentiation (3).

Lesions linked with medication-related osteonecrosis of the jaws (MRONJ) are resistant to many therapeutic options. As a result, alternative treatments capable of enhancing patient outcomes should be investigated. Leukocyte- and platelet-rich fibrin (LPRF) is a second-generation platelet concentrate composed of natural autologous fibrin matrix. It exhibits anti-infective activity via immunological modulation and accelerates the angiogenesis and multiplication of fibroblasts and osteoblasts; as a result, it promotes soft tissue repair and reduces alveolar bone exposure in the oral cavity. As a result, this could be a noninvasive, rapid, and novel technique to managing bone exposure. The LPRF membrane contributes to a favorable outcome by acting as a physical barrier against microorganisms, preventing secondary infections (4).

Cellular therapy is a new treatment option in regenerative endodontics. Allogeneic mesenchymal stromal cells were tested for their ability to stimulate dental pulp and apical bone regeneration in an endodontically treated tooth. After 14 months after MSC transplantation, the tooth being studied demonstrated sensitivity to cold and electric pulp testing. Radiographic and cone-beam computed tomography images revealed improved periapical bone density, healing of the periapical lesion, and nearly complete apical remodeling. Thus, allogeneic MSCs could be a first-line therapy in regenerative endodontics (5).

The purpose of our research was to investigate the effects of stimulating and inhibiting multiple intracellular functional pathways of senescent gingival fibroblasts in culture, in the presence of microvesicles released by pluripotent stem cells derived from mesenchymal stem cells and platelet-rich plasma.

MATERIALS AND METHODS

The laboratory research aimed to quantify the evolution of the degree of senescence of gingival fibroblasts (senescent cells) by evaluating β-galactosidase through flow cytometry (6, 7) in a biculture, in the presence of platelet-rich plasma and pluripotent stem cells, repro-

grammed from mesenchymal stem cells (in culture), or under the action of exosomes/micro vesicles released from MSC-iPSCs, in the form of concentrated supernatant, administered in the culture medium.

Storage rat gingival fibroblasts (cell line no. 1) were cultivated under conventional laboratory conditions and analyzed for β-galactosidase using flow cytometry after passages 1, 10, 20, and 30. To obtain senescent gingival fibroblasts, they were treated with ultraviolet (λ=315 nm, 80 mJ/cm^2) and multiplied through 30 consecutive passes.

To produce MSC-iPSCs, we used the episomal technique with iPSC reprogramming vectors and the appropriate Stemline culture media (Invitrogen), in accordance with the manufacturer's instructions. We picked this method since the usage and manipulation of potentially genetic material, which is mentioned in the "dangerous" chapter, is completely prohibited. The growth and multiplication of pluripotent stem cells reprogrammed from mesenchymal stem cells were carried out utilizing an Alvetex 3D bio support -a gift from Reinnervate-, as previous investigations revealed the highest efficiency for this form of support (8).

The platelet-rich plasma (PRP) gel was prepared as previously described (9) and delivered at a concentration of 1%.

For exosome separation, the culture medium of pluripotent stem cells produced from rat aortic smooth muscle cells was centrifuged at 100,000 x g (10).

The following compounds were employed in tests and protocols with senescent gingival fibroblasts: 1 µM LY294002, 1 µM nutlin-3, 1 µM berberine, 1 µM resveratrol, 1 µM lipopolysaccharide (LPS), 1 µg/ml collagen, 1 µM thrombin, and 1 µg/ml fibrinogen.

All experimental results obtained during the current study were processed entirely by statistical methodologies, using a number of well-known and optimized tests over time and for medical research, among which the One-Way ANOVA test should be mentioned, which was also supplemented, on occasion, with the Student-Newman-Keuls test.

All the experiments were approved by the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy from Iaşi.

RESULTS

The best qualitative and quantitative development in the case of pluripotent stem cells experimentally reprogrammed from mesenchymal stem cells, beginning with the second passage in culture, was obtained when we multiplied them in a preconditioning medium containing only 1% O2 (8), as previously demonstrated. We always assumed a 100% increase (n=5 experiments per set, data not shown, personal observation).

In addition, the most important β-galactosidase reduction effects in senescent gingival fibroblasts in monoculture were observed in the presence of exosomes/micro- vesicles at a concentration of 0.01%, obtained in concentrated form by ultracentrifugation of the MSC-iPSC supernatant. These latter cell types were also developed in a medium preconditioned with 1% O2. We observed a 20% drop in β-galactosidase levels in senescent gingival fibroblasts under these circumstances, consistent with earlier studies.

In the first series of tests, senescent gingival fibroblasts were treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet-rich plasma.

Previously, MSC-iPSCs were treated with 1 μM LY294002, a highly selective PI3K kinase inhibitor. In senescent gingival fibroblasts, we observed an average 15% drop in β-galactosidase activity (fig. 1).

In the second series of tests, a separate batch of senescent gingival fibroblasts was treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet rich plasma. Previously, MSC-iPSCs were treated with 1 μM nutlin-3, which effectively stabilized the non-genomic activities of p53 (MDM2/p53 pathway). Senescent gingival fibroblasts showed an average 13% drop in β-galactosidase levels (fig. 1).

In the third series of tests, a large number of senescent gingival fibroblasts were treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet rich plasma. MSC-iPSCs were treated with 1 μM berberine, which inhibits ROS-dependent and JNK-driven cell death via PI3K/Akt. We observed a 23% drop in β-galactosidase levels in senescent gingival fibroblasts (fig. 1).

In the fourth series of studies, a completely separate batch of senescent gingival fibroblasts were treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet-rich plasma. MSC-iPSCs were treated with 1 μM resveratrol, potentially improving their survival, self-renewal, lineage commitment, and anti-aging benefits. In senescent gingival fibroblasts, we observed an average 52% drop in β-galactosidase levels (fig. 1).

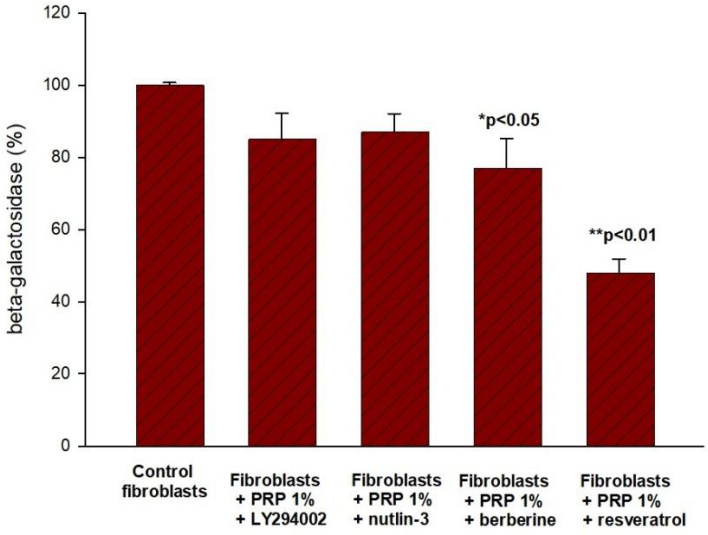

Fig. 1. Determination of β-galactosidase in senescent gingival fibroblasts, when cultured with 0.01% exosomes obtained from the supernatant of MSC-iPSC and 1% platelet-rich plasma. Previously, MSC-iPSCs have been treated with 1 μM LY294002, nutlin-3, berberine, and resveratrol. (*p<0.05 as compared to the normal culture medium. **p<0.01 as compared to the normal culture medium)

In the fifth series of tests, senescent gingival fibroblasts were treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet-rich plasma. Previously,

MSC-iPSCs were treated with 1 μM lipopolysaccharide (LPS), which induces a proinflammatory profile on iPSC-MSC. We observed a 37% drop in β-galactosidase levels in senescent gingival fibroblasts (fig. 2).

In the sixth series of studies, a separate batch of senescent gingival fibroblasts was treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet rich plasma. Previously, MSC-iPSCs were treated with 1 μM collagen, which increased chemokine and growth factor production by MSCs. We observed a 61% drop in β-galactosidase levels in senescent gingival fibroblasts (fig. 2).

In the seventh series of tests, a large number of senescent gingival fibroblasts were treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet rich plasma. MSC-iPSCs were treated with 1 μM thrombin, which increases fibronectin production through protease-activated receptor-mediated signaling pathways. In senescent gingival fibroblasts, we observed an average 58% drop in β-galactosidase levels (fig. 2).

In the eighth series of trials, a completely separate batch of senescent gingival fibroblasts was treated with 0.01% exosomes derived from MSC-iPSC supernatant and 1% platelet rich plasma. Previously, MSC-iPSCs were treated with 1 μM fibrinogen, which promotes self-renewal by stabilizing bFGF and activating autophagy. We observed a 48% drop in β-galactosidase levels in senescent gingival fibroblasts (fig. 2).

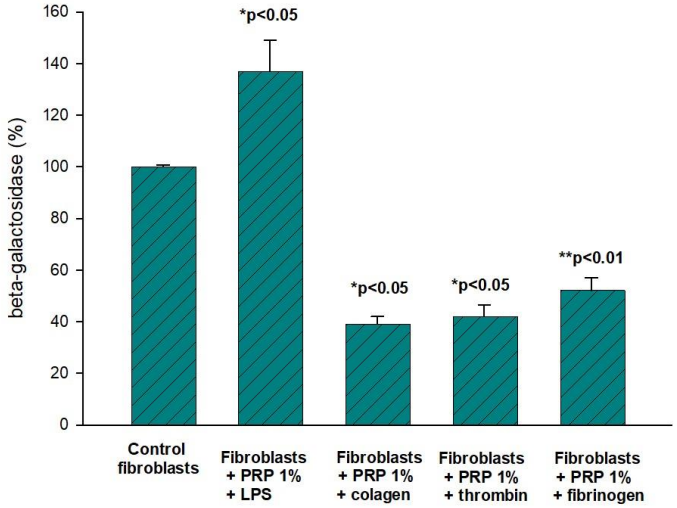

Fig. 2. Measurement of β-galactosidase in senescent gingival fibroblasts, when developed in the presence of 0.01% exosomes obtained from the supernatant of MSC-iPSC and 1% platelet-rich plasma. Foregoing, MSC-iPSCs have been treated with 1 μM LPS, collagen, thrombin, and fibrinogen. (*p<0.05 as compared to the normal culture medium. **p<0.01 as compared to the normal culture medium)

DISCUSSION

There are studies underway to investigate platelet-rich plasma (PRP) effects in human mesenchymal stem cells, which may support or limit the clinical use of MSCs in conjunction with PRP. The effects of PRP

on proliferation, migration, stemness, the preservation of MSC immune-modulatory capabilities, and the emergence of the senescence phenotype were investigated. Overall, PRP promotes MSC proliferation, maintains multipotency, and does not impede with lineage differentiation. PRP (platelet lysate or releasate) protects MSCs' immune-privileged potential and may postpone the onset of the senescent phenotype. Currently, there is little evidence tying specific chemicals to biological mechanisms. Several knowledge gaps must be addressed in order to gather enough usable information for translation (11).

Platelet-rich plasma is defined as an enriched platelet suspension in plasma. In addition to its clinical applications in numerous orthopedic illnesses and beyond, PRP and platelet lysate (PL) have received attention in the field of tissue engineering. PRP has been used for a variety of tissue engineering applications, including bone, cartilage, skin, and soft tissue repair, with the majority of studies focused on bone tissue engineering. These methods take advantage of either the release of chemo attractive, angiogenic, proliferative, and potentially pro-regenerative growth factors from PRP, or the hydrogel properties of activated PRP, which make it suited as a cell delivery vehicle. Many of these researches combine PRP with biomaterials, cells, and, in some cases, recombinant growth factors. Although the experimental design frequently does not allow for judgments on the pro-regenerative effect of PRP, the majority of articles show positive results when PRP is introduced to the tissue-engineered construct. Furthermore, it was established that the release of growth factors from PRP can be customized and regulated by combining PRP with growth factor-capturing materials. Platelet-derived preparations (PRP and PL) are a promising source of autologous growth factors that can be used as a cell culture supplement or to induce regeneration in tissue-engineered constructions. Furthermore, activated PRP shows promise as an autologous cell carrier. However, research exploring PRP in these circumstances frequently provide inconsistent results, which are most likely due to a lack of standardized preparation methods, notably in terms of platelet composition and donor variance. Finally, the use of PRP must be customized for each application (12).

Soft tissue abnormalities can be treated using autologous fat grafts or adipose-derived stem cells (ASCs). However, the results are inconsistent and can include tissue resorption and necrosis. This could be owing to poor vascularization. Platelet-rich plasma (PRP) contains concentrated autologous platelets. Platelet-derived growth factors and cytokines can promote angiogenesis. The concomitant use of PRP may boost the regeneration potential of fat grafts. The ideal ratio has yet to be identified. PRP preparation produces platelet-poor plasma (PPP). PRP and PPP can both be utilized to increase ASCs in cell culture without the use of xenogeneic chemicals. A PRP concentration greater than 20% exerts inhibitory effects (13).

Platelet-rich plasma (PRP) is a biological therapy that stimulates biological processes like cell growth. The extent of PRP's effect is determined by a variety of parameters, the most important of which is the composition of PRP. The study aimed to investigate the correlation between cell proliferation and growth factors (namely IGF-1, HGF, PDGF, TGF-β, and VEG) in platelet-rich plasma. First, PRP's composi-

tion and effect on cell proliferation were compared to platelet-poor plasma (PPP). The association between each PRP growth factor and cell proliferation was then investigated. Cell proliferation was greater in cells treated with PRP lysates than in cells treated with PPP lysates. PRP showed considerably greater levels of PDGF, TGF-β, and VEGF. When the PRP growth factors were examined, only IGF-1 showed a significant correlation with cell proliferation. IGF-1 levels were the only ones that did not link with platelet levels. The extent of PRP's effect depends not only on platelet count, but also on platelet-independent molecules (14).

Platelets produce platelet growth factors (as PDGF, IGF-1, EGF-, HGF, TGFβ, bFGF, and VEGF) that regulate wound healing at all stages. These chemicals are derived from platelet-rich plasma. Over the last five decades, there has been a substantial growth in interest and utilization of platelets' regenerative qualities in a variety of medical sectors around the world. PRP and PRF derived preparations are used in dentistry, sports medicine, as well as dermatology, and cosmetology to treat alopecia, further hair reconstruction (FGF-7, HGF), acne scars, skin so in rejuvenation and regeneration, chronic wounds, burns, and acquired vitiligo. Another important domain is represented by gynecology and reproductive medicine (as treatment of infertility, but also erectile dysfunction - using PDGF-β, TGF-β, IGF-1, sexual dysfunction - PDGF, vaginal atrophy). Ophthalmology is becoming more and more important from the point of view of using platelet-rich plasma derivatives (as healing of corneal epithelial wounds, dormant corneal ulcers, dry eye syndrome and, last but not least, corneal surface reconstruction). Treatments in neurology are involving also substances obtained from platelet-rich plasma (speaking about regeneration of neurons, pain relief, and clinical symptoms -through the use of TGF-β 1, IGF-1, PDGF, VEGF, and FGF). So, platelet-rich plasma therapy is a very interesting alternative and supplement to established treatment procedures. However, the potential use of platelets is not entirely known. Many factors influence the composition of platelet-rich plasma, which can have an impact on its efficacy and clinical advantages. Additional study is required to standardize PRP delivery preparation protocols and strategies for a specific disease entity or clinical instance (15).

Mesenchymal stem cells (MSC) added to bone replacement materials can aid in bone repair. Bone development in bio composites is highly reliant on the type of biomaterial, its pre-treatment, and the cells used. Supplements that may be immunogenic or infectious, such as fetal calf serum (FCS), should not be used in cell expansion media. Cells cultured in two different mediums were examined on several biomaterials for bone forming capacity following ectopic implantation in vivo, as well as growth rate and differentiation capacity in vitro. The replacement of FCS with PRP removed the hazards associated with the use of xenogeneic supplements. It increased the expansion of MSC and retained their differentiation and in vivo bone forming potential in an environment suitable for autogenous usage (16).

Implant therapy is a popular therapeutic option in dentistry and orthopedics, however it is frequently accompanied with an increased risk of microbial contamination of the implant sites, which can cause bone tissue damage. This work intends to create two silver-enriched platelet-rich plasma (PRP) multifunctional scaffolds that can

prevent implant-associated infections while also boosting bone repair. In vitro tests were conducted on both commercial silver lactate (L) and freshly synthesized silver deoxycholate: β-Cyclodextrin (B). Initially, the antibacterial activity of the two silver soluble forms and PRP supplemented with the two silver forms was investigated on microbial planktonic cells. At the same time, the biocompatibility of silver-enriched PRPs was evaluated using an MTT test on human primary osteoblasts (hOBs). Following that, a study was done to assess the efficacy of various concentrations and types of silver-enriched PRPs in suppressing microbial biofilm formation and boosting hOB differentiation. PRP-L (0.3 μg/mm2) and PRP-B (0.2 μg/mm2) inhibit planktonic cell proliferation and biofilm formation in Staphylococcus aureus, Staphylococcus epidermidis, and Candida albicans, while retaining hOB viability and differentiation capability. As a partial conclusion, the results obtained suggest that L- and B-enriched PRPs could constitute a promising preventive strategy against biofilm-related implant infections and can be used as a new silver formula that, in addition to increasing fibrin binding protecting silver into the truncated cone-shaped cyclic oligosaccharides, to be able to achieve comparable inhibitory results on prokaryotic cells, but with a lower concentration (17).

Regulatory authorities oppose the use of fetal bovine serum (FBS) as a cell culture supplement in order to reduce the danger of zoonotic and xenogeneic immunological reactions in the transplanted host. Furthermore, FBS production has come under fire because to animal welfare problems. Platelet derivatives have been proposed as FBS alternatives for the ex-vivo expansion of mesenchymal stem/stromal cells (MSCs), as platelet-derived growth factors can enhance MSC multiplication. Platelet-derived growth factors can be found in platelet lysate (PL), which is generated by freezing and thawing platelet-rich plasma repeatedly or by adding physiological stimuli such as thrombin or CaCl2.PL-expanded MSCs have already been used in clinical trials, taking advantage of their quicker proliferation compared to FBS-expanded preparations. If PL is used to other biopharmaceutical drugs, demand is anticipated to skyrocket. The use of fresh platelet units in the manufacturing of PL poses problems because to the scarcity of platelet donors. Expired units could be an option, however further information is needed to determine safety, including pathogen decrease, and usefulness of the obtained PL. Furthermore, significant problems about the establishment of PL release criteria, such as the concentration ranges of certain growth factors in PL batches for different therapeutic reasons, must be addressed. We are still distant from a uniform definition of PL and standardized PL production due to our poor knowledge of the processes that drive PL-promoting cell proliferation (18).

Dental pulp stem cells (DPSCs) are intriguing candidates for therapeutic use due to their high proliferative capability, multipotent differentiation, immunomodulatory properties, and lack of ethical problems. Clinical research on DPSCs is still in its early phases. The failure to obtain clinically effective results may be due to issues with the DPSC production process. Cell properties may be impacted by differences in DPSC preparation procedures and reagent formulas, resulting in conflicting experimental outcomes. The preparation of clinical-grade DPSCs is far from complete. To reach therapeutic use, it is required to transition the manufacture of stem cells

from laboratory to clinical grade (19).

Human platelet lysate (PL) as well as human platelet lysate serum (PLS) are used as cell culture supplements instead of fetal bovine serum (FBS) due to ethical concerns, batch variability, and the possibility of introducing xenogenic pollutants. Some studies examined the content and efficiency of PL, PLS, as well as FBS as supplements during the culture and cryopreservation of human gingival fibroblasts, also Wharton's jelly-derived mesenchymal stem cells (WJ-MCS), and finally adipose tissue (AdMSC). Biochemical components, certain growth factors, and cytokines were examined in each of them; additionally, the cells were cultivated in media supplemented with 5% PL, 5% PLS, and 10% FBS and exposed to various freezing and thawing solutions containing the supplements under investigation. Biochemical parameters in PL and PLS were found to be similar to those in FBS, with some variations in fibrinogen and calcium concentrations. PL and PLS contained higher levels of growth factors and cytokines than FBS. Cell proliferation and morphology did not differ significantly between the three culture mediums. PLS and FBS provided better results for cell cryopreservation and thawing. To summarize, PL and PLS are an ideal choice to substitute the conventional supplement of animal origin (FBS) in the media necessary for the culture and cryopreservation of fibroblasts, WJ-MSC, and AdMSC (20).

CONCLUSIONS

Exosomes were found to reduce β-galactosidase concentrations in senescent gingival fibroblasts by around 20% on average. Exosomes were also delivered in combination with: LY-294002 (a non-selective inhibitor of phosphatidylinositol 3-Kinase (PI3K) pathway, α/δ/β, 15% on average); nutlin-3 (a potent and selective small-molecule MDM2 antagonist that activates p53, 13% on average); berberine (which protects against MSC apoptosis by preventing ROS-dependent, as well as JNK-driven cell apoptosis, in a PI3K/Akt-dependent manner, 23% on average); resveratrol (may improve the therapeutic effects of MSCs by enhancing their survival, as well as self-renewal, lineage commitment, and anti-aging effects, 52% on average); collagen (promotes the secretion of the chemokines and growth factors by MSCs, 61% on average); thrombin (promotes fibronectin secretion by MSCs via the protease-activated receptor mediated signaling pathways, 58% on average); and fibronectin (supports self-renewal of MSCs through stabilization of bFGF and activation of autophagy, 48% on average. On the other side, lipopolysaccharide (which might induce a proinflammatory profile on iPSC-MSC) enhanced the production of β-galactosidase (37% on average).

All of these findings suggest that exosomes derived from pluripotent stem cells induced from mesenchymal stem cells and administered in the culture medium of senescent gingival fibroblasts can influence the degree and evolution of senescence in these cells by potentiating, activating, or stimulating some intracellular biological signal transduction pathways, particularly those involving resveratrol, collagen, thrombin, and fibronectin.

COMBINED RELUGOLIX TREATMENT FOR HIGHLY SYMPTOMATIC UTERINE LEIOMYOMA PATIENTS (Abstract): Many conservative treatments for symptomatic uterine leiomyoma have been proposed but in the large majority of cases these are often limited by the associated side effects. A relative novel treatment with GnRH antagonists has been reported in the literature with good results. The primary goal was to assess the degree of reduction of uterine global volume and largest uterine fibroma volume at the end of 24 weeks of combined treatment with Relugolix 40 mg, 1 mg estradiol and 0.5 mg norethindrone acetate as well as at 12 weeks after. The secondary goal was to subjectively assess the reduction of vaginal bleeding during treatment and the evolution of hematologic parameters. **Materials and methods:** We analyzed 5 patients with uterine leiomyoma with heavy menometrorrhagia and severe anemia. 4 cases rejected the surgical treatment and 1 case was not suitable for surgery due to morbid obesity and associated pathology. All cases accepted the combined therapy with relugolix 40 mg, 1 mg estradiol and 0.5 mg norethindrone acetate for a period of 24 weeks. **Results:** In all cases, the reduction of uterine and largest leiomyoma volume was consistent after 24 weeks of treatment and maintained so even 12 weeks after. In addition, the severity of vaginal bleeding was also reduced, so that the hematologic parameters slowly improved. **Conclusions:** Combined therapy with relugolix 40 mg, 1 mg estradiol and 0.5 mg norethindrone acetate is a very good alternative especially in cases where surgery is not accepted or is not suitable due to associated morbidity. **Keywords:** LEIOMYOMA, MENOMETRORRAHAGIA, SEVERE ANEMIA, RELUGOLIX.

INTRODUCTION

Uterine leiomyoma, known in medical practice as uterine fibroid, is the most common form of benign tumor of the uterus. It is also known that the prevalence of this tumor reaches its maximum rates among women in the reproductive period (15-50 years old women) (1, 2) and its development and growth is highly dependent of hormonal factors; throughout

life, approximately two out of three women, especially between 30 and 50 years of age, will develop this type of pathology (3).

Cases of uterine fibroids in the prepubertal period have not been described in literature, and cases found among teenage girls have rarely been found. The maximum incidence is found among Afro-American women in their fifties. In Caucasian population, the incidence is reached by women the ages of 30 and 40. Currently, there is not enough information to clarify the rate of occurrence of uterine fibroids among Hispanic and Asian women (4).

The incidence of these tumors is firstly connected to the hormonal activity (5) and this is sustained by the association of this pathology with nulliparity/infertility, early menarche and late menopause. Heredity, race and age are also important risk factors (5). Other risk factors such as heart disease, especially hypertension, smoking, alcohol consumption, oxidative stress, have not been sufficiently documented.

This pathology is often neglected by patients, many of them are presenting with large pelviabdominal tumors, heavy vaginal bleeding and severe anemia.

Although the definitive treatment remains hysterectomy, conservative treatments are recently widely accepted, and these are mostly sustained by the desire of the patients to preserve the uterus and thereby fertility. The main goals of the conservative treatment are to reduce the symptoms and to diminish the size of the leiomyomas (6).

Despite being the first-line medical treatment for uterine fibroids, there is little evidence to support the use of contraceptives (7).

Although leuprolide acetate and other injectable long-acting gonadotropin-releasing hormone (GnRH) agonists (8) are effective, their duration of use is limited by hypoestrogenic sequelae, which may need the use of supplementary hormonal therapy to offset adverse effects.

The selective progesterone-receptor modulator - ulipristal acetate - is recommended by the European Medicines Agency to be used for the treatment of uterine fibroids only in premenopausal women in whom surgical procedures (including uterine fibroid embolization) are not appropriate or have not worked. However, its use must be very cautious since there are reported rare cases of serious liver injury (9).

The GnRH antagonist elagolix is licensed for the treatment of uterine fibroids for a period of 24 months and lowers excessive menstrual flow in women with uterine fibroids when taken with estradiol and norethindrone acetate (10). However, due to its short half-life, elagolix must be taken twice daily. Its use has been linked to negative effects on blood pressure, cholesterol and liver enzyme levels, and bone mineral density at one year (10, 11).

Relugolix and linzagolix are new GnRH antagonists which have been demonstrated high efficiency in the treatment of symptomatic leiomyoma patients (12, 13).

MATERIALS AND METHODS

This study reflects our experience with combined relugolix therapy for highly symptomatic uterine leiomyoma patients.

Our case series included five patients that addressed to Obstetrics and Gynecology 2nd Clinic, “Sf. Ap. Andrei” Clinical Emergency County Hospital Galati, between the 1st of November 2023 and 31st of March 2024 for heavy vaginal bleeding and

severe anemia due to large uterine leiomyomas. After initial assessment, in all cases dilatation and curettage (D&C) with hemostatic and bioptic indication was performed along with hematologic reanimation (in three cases blood transfusions were indicated).

Ultrasound endovaginally scan was performed in all cases using a *General Electric Voluson* S8 equipment. Uterine volume as well as the volume of the largest leiomyoma were noted in all cases.

Surgical treatment - total hysterectomy - was proposed and categorically refused by 3 patients. In the remaining two cases, due to morbid obesity sustained by BMI above 40, conservative treatment was our first choice.

All five cases in our study were treated with a combination of relugolix 40 mg, 1 mg estradiol and 0.5 mg norethindrone acetate for 24 weeks. The patients were clinically and ultrasonographical assessed at the beginning of the trial, at the end of the pharmacological treatment in week 24, and again 12 weeks from stopping the treatment.

RESULTS

The cases under investigation were white female, 42 to 50 years of age. Body mass index (BMI) was above 30 in all cases (mean 39.74 ± 5.03). In 2 patients, in which associated morbidity such as diabetes or cardiac disease were also noticed, the BMI was even above 40 (tab. I).

TABLE I.

Clinical and paraclinical features of the cases.

BASELINE CHARACTERISTICS	Case 1	Case 2	Case 3	Case 4	Case 5
Age(years)	42	48	50	46	49
Race	White	White	White	White	White
Region	Europe	Europe	Europe	Europe	Europe
BMI (kg/m^2)	33.4	36.7	45.8	39.2	43.6
MBL - (No. of pads/tampons)					
0 w	10	9	12	11	12
24 w	5	7	7	8	7
36 w	4	7	6	7	6
Uterine volume (cm^3)					
0 w	210.23	390.73	449.89	381.47	472.9
24 w	186.8	320.7	387.8	317.6	394.1
36 w	172.5	304.9	367.2	308.5	379.4
Volume of largest leiomyoma (cm^3)					
0 w	53.52	85.76	112.69	66.1	113.92
24 w	41.6	63.8	79.2	49.6	75.6
36 w	39.7	58.5	71.4	43.8	67.8
Hemoglobin concentration (g/dL)					
0 w	7.8	8.5	5.7	8.2	6.8
24 w	9.6	9.8	9.2	9.7	9.4
36 w	9.8	10.1	9.6	10.0	9.8

BMI - body mass index; MBL - menstrual blood loss.

All cases presented with a history of severe menstrual and/or intermenstrual bleeding, which was subjectively assessed by the number of absorbent pads used daily. In our group, the number of pads used in the heaviest day of vaginal bleeding was between 9 to 12 per day. During the combined treatment with relugolix, the number of pads used was progressively lower so that, at the end of 24 weeks of treatment this number ranged between 5 to 8. Moreover, 12 weeks after the initial treatment, vaginal bleeding was reasonable, with a number of absorbent pads between 4 to 7 daily (tab. I).

The reduction of vaginal bleeding along with the hematological treatment were the key factors for correction of severe anemia. At the start of the trial, the patient's hemoglobin levels ranged between 5.7-8.5 g/dL (mean 7.4 ± 1.14). After 24 weeks of combined treatment the hemoglobin values improved, ranged between 9.2-9.8 g/dL (mean 9.54 ± 0.24), and maintained above 9.6 g/dL (ranged between 9.6-10.1 g/dL, mean 9.86 ± 0.19) at 12 weeks after stopping the treatment (tab. I).

Positive outcomes were additionally noticed in terms of uterine global volume and the volume of the largest uterine leiomyoma (figs. 1, 2).

When combined therapy with relugolix was initiated, the global uterine volume of the cases ranged between 210.23 and 472.9 cm^3 (mean 381.04 ± 103.01) and the greatest leiomyoma's volume between 53.52 and 113.92 cm^3 (mean 86.39 ± 27.12). A decrease of the global uterus volume was recorded in all cases with limits between 37.73 and 93.5 cm^3. Additionally, compared to day 0, the greatest leiomyoma's volume was much smaller at week 36, with values between 39.7 and 71.4 cm^3, the range of recorded reduction being between 13.82 to 46.12 cm^3 (tabs. I, II, figs. 1, 2).

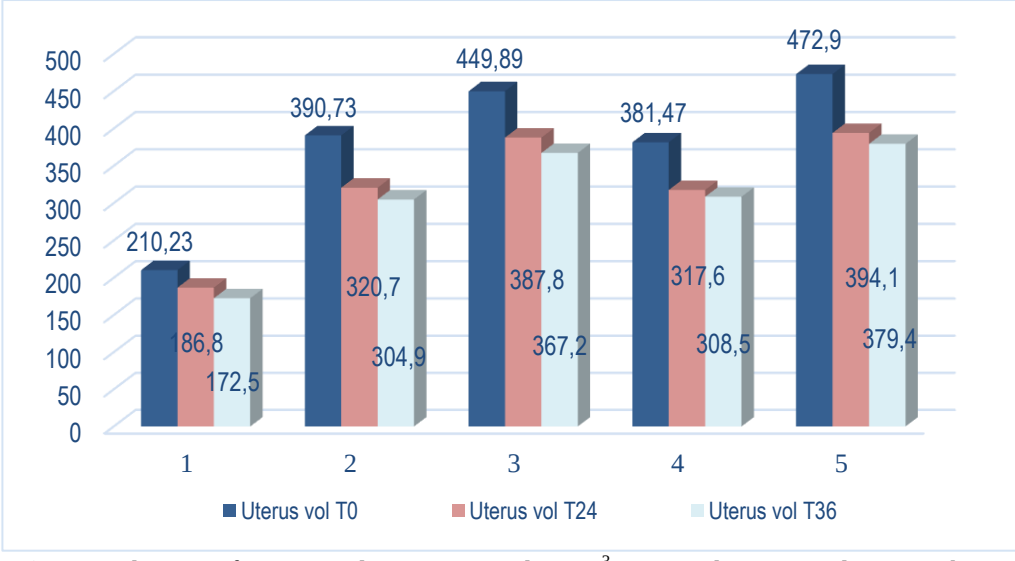

Fig. 1. Reduction of uterine volume expressed in cm^3 at 24 and respectively 36 weeks from the beginning (T0) of combined therapy with relugolix.

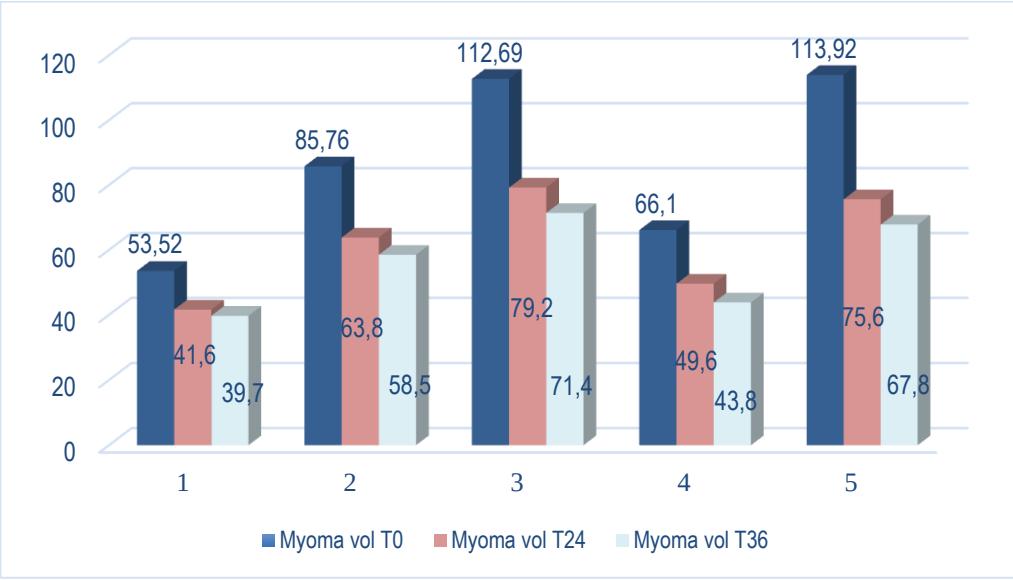

Fig. 2. Volume reduction of the largest uterine leiomyoma expressed in cm^3 at 24 and respectively 36 weeks from the beginning (T0) of combined therapy with relugolix.

TABLE II.

Study results evaluated at the beginning of treatment (T0), after 24 weeks (T24) of combined therapy, and after 36 weeks (T36) from the enrolment.

	TIME OF EVALUATION		
CHARACTERISTICS	**T0**	**T24**	**T36**
Uterine volume (cm^3)	381.04 ± 103.01	321.4 ± 83.4	306.5 ± 82.09
Volume of the largest uterine myoma (cm^3)	86.39 ± 27.12	61.96 ± 16.23	56.24 ± 14.11
Hemoglobin concentration (g/dL)	7.4 ± 1.14	9.54 ± 0.24	9.86 ± 0.19
Values are expressed as mean ± SD			

The treatment was well tolerated by the patients, none of them reported significant side effects.

DISCUSSION

Current studies regarding the conservative treatment of highly symptomatic uterine leiomyoma focus on the use of relugolix. This is a GnRH receptor antagonist that can be administered in daily doses and has the effect of blocking the binding and signaling of endogenous GnRH and thus leading to reversible, dose-dependent decreases in gonadotropin concentrations and subsequent suppression of the ovarian production of estradiol and progesterone.

Following two international studies, LIBERTY 1 and LIBERTY 2, that used combined therapy (relugolix, estradiol and norethindrone acetate) with daily administration, a significant decrease in menstrual bleeding was observed compared to the placebo group (12). Specifically, according to Al-Hendy *et al*, more than 70% of wom-

en with heavy uterine bleeding enrolled have reported a significant reduction of menstrual bleeding. Compared with placebo group, the mean reduction of menstrual blood loss was as much as 84.3% (12). Despite the fact that we did not used an objective method to quantify the amount of menstrual blood lost, the subjective assessment based on number of pads or tampons used in the heaviest day of menstrual bleeding suggests the same positive effect of the therapy.

The reduction of significant vaginal bleeding along with specific hematological treatment should eventually correct the anemic syndrome and thus, assuring a better physical condition for the patients. As we found in our study, other reports from the literature emphasize the significant increase in hemoglobin levels after relugolix combined therapy. In a recent observational study, Muzii *et al.* reported an increase in hemoglobin levels by 25% after 3 months of combined therapy, from 9.3 ± 1.1 to 11.6 ± 1.7 g/dL (14).

Moreover, after 24 weeks of relugolix combined therapy, patients should experience not only an improvement in the quality of life by reducing symptoms related to pelvic pain, heavy menstrual bleeding, oxidative stress but also an improvement in sexual life (12).

As in case of GnRH agonists (15, 16, 17), the use of GnRH antagonists with a concomitant hormonal add-back therapy has the same effect in reduction of uterine as well as myoma volumes but with less secondary effects associated with hypoestrogenism (14).

In a recent multicentric observational study published by Muzii *et al.*, the reduction of mean uterine volume after 3 months of combined relugolix therapy was as much as 26%. In addition, the reduction in diameter of the largest myoma was noted as much as 14% (14).

Although limited by the number of cases, our study reports near similar results. The mean uterine volume decreased from 381.04 ± 103.01 cm^3 at the enrolment to 321.4 ± 83.4 cm^3 after 24 weeks of combined treatment, corresponding to a 15.6% decrease, and again to 306.5 ± 82.09 after another 12 weeks of surveillance, corresponding to a 19.56% decrease. Moreover, the mean largest myoma volume decreased from 86.39 ± 27.12 cm^3 at the enrolment to 61.96 ± 16.23 cm^3 after 24 weeks of treatment, corresponding to a 28.27% decrease, and again to 56.24 ± 14.11 cm^3 after another 12 weeks of surveillance, corresponding to a 34.89% decrease. Despite the fact that reductions in uterine as well as in myoma`s volume were recorded in all patients, the most important degree of reduction noticed in our group was in patients with the largest uterus and largest myomas.

Moreover, the more significant degree of reduction of the uterine myomas when compared to the degree of reduction of global uterine volume could be explained by the very well-known facts that both estradiol and progesterone are essential for myoma development and these tumors are more responsive to sex steroids than normal myometrium (18).

We are in consensus with other recent reports from the literature on the fact that relugolix combined therapy could be used as a presurgical treatment as well, in order to reduce the volume of the uterus and myomas and thus to enable an improved surgical field, a less invasive surgical procedure or even postpone or amend the surgical treatment at all. In a recent study

from the literature, from the total number of 31 patients scheduled for surgery because of abnormal uterine bleeding associated with uterine myomas enrolled, in 4 patients (13%) the surgical procedure was shifted after 3 months of relugolix combined therapy to a less invasive approach (hysteroscopic myomectomy and laparoscopic hysterectomy) whereas in 8 patients (26%) the surgical treatment was temporarily avoided in favor of medical therapy for another 3 additional months (14).

Recent trials focus on efficacy and safety of long-term relugolix combined therapy. In a recent report published by Al-Hendy *et al*, from a total of 610 patients who were enrolled and completed LIBERTY trials, a number of 363 patients completed an additional 28 weeks of relugolix combined therapy (19). The reported results were very good and encouraging. 87.7% of patients with continuous 52 weeks of combined therapy had a sustained improvement in menstrual bleeding. Additionally, long-term combined therapy was also associated with a sustained reduction of other uterine leiomyoma symptoms and with a modest but continued reduction of uterine and leiomyoma volumes at week 52 when compared with week 24 of treatment (19). According to the same study, long-term relugolix combined therapy was generally well tolerated, headaches and hot flushes being the most frequent reported side effects (19).

CONCLUSIONS

Relugolix combined therapy proved to be very effective in patients with heavy vaginal bleeding associated with uterine leiomyomas. Clinical symptoms and anemic syndrome are significantly reduced after 24 weeks of treatment and maintained so even 12 weeks after. This therapy should always be taken into consideration in highly symptomatic leiomyoma patients who do not agree or are not suitable with surgical management or as preoperative medical treatment in order to reduce the uterine and myomas volumes and thus assuring a safer and perhaps more conservative approach. Despite our little number of cases, the results are similar to other reports from the literature. More studies have to be done in order to establish the efficacy and safety of long-term treatment.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

A STUDY ON PHYSICIANS' ATTITUDES DURING THE RESOLUTION PROCESS OF MEDICAL MALPRACTICE COMPLAINTS

A STUDY ON PHYSICIANS' ATTITUDES DURING THE RESOLUTION PROCESS OF MEDICAL MALPRACTICE COMPLAINTS (Abstract): Complaints filed against physicians represent an increasingly debated issue in both the medical and legal fields. In recent years, there has been a marked rise in the number of complaints submitted against healthcare professionals, which has contributed to a growing interest in the study of this phenomenon. The aim of our research was to explore and understand physicians' attitudes throughout the process of resolving medical malpractice complaints. **Materials and methods:** To achieve this objective, we conducted a qualitative study using semi-structured interviews. The participants were lawyers with substantial experience in handling medical malpractice cases. **Results:** A total of 14 lawyers participated in the study. Thematic analysis of the collected data led to the identification of 9 themes and 21 subthemes. This article focuses on the attitudes displayed by physicians during the malpractice complaint resolution process. According to the lawyers interviewed, physicians generally exhibited a negative attitude during procedures related to malpractice claims. This behavior is attributed to several factors, including the absence of a well-structured legal framework and the psychological pressure associated with involvement in judicial proceedings related to professional liability in healthcare. **Conclusions:** Our findings suggest the need for a mechanism that supports both the patient and the physician, enabling the latter to adopt a more open and constructive approach during professional liability procedures. Such a system could facilitate the resolution of medical malpractice complaints in a manner that minimizes the emotional and professional impact on all parties involved. **Keywords:** MEDICAL MALPRACTICE, PHYSICIANS, LAWYERS, QUALITATIVE RESEARCH.

INTRODUCTION

Medical errors are considered inevitable events within the practice of medicine (1), often generating consequences in the realm of professional liability. According to a study conducted in the United States in 2024, 38.2% of physicians surveyed admitted to having been involved in disputes related to medical malpractice within the past decade (2)

Legislation provides protection for patients (3). Safeguarding patient rights is a natural and necessary aspect of medical practice, as it reinforces physician accountability within the therapeutic relationship. At times, treatments may not yield the

expected outcomes, resulting in harm or injury to the patient.

Medical malpractice has increasingly become a subject of interest among scholars and professionals (4). According to data from the literature, involvement in legal proceedings is an especially stressful experience for physicians (5), which may help explain certain attitudes adopted by doctors during the resolution of malpractice complaints filed against them.

The aim of our study was to explore and identify the attitudes of physicians throughout the process of reviewing and resolving medical malpractice complaints submitted by patients or their families.

MATERIALS AND METHODS

To achieve the aim of this research, we employed a qualitative research methodology. Data were collected through semi-structured interviews. The target population consisted of lawyers who had handled at least one case involving a medical malpractice complaint.

Both male and female participants were included in the study, with no selection criteria based on years of experience in the profession, as this variable was not considered relevant to our research objectives.

Prior to participating, all respondents were informed about the purpose, objectives, and procedures of the study and provided written informed consent.

The initial part of the interview comprised introductory questions concerning the participants' legal specialization, their motivation for choosing this area of law, and their experience and number of cases handled in the field of medical malpractice litigation. The interview consisted of a set of 19 open-ended questions.

Among them were questions regarding physicians' attitudes during the resolution of malpractice complaints, as well as inquiries related to alternative dispute resolution methods in medical malpractice cases.

All interviews were fully transcribed and analyzed using *NVivo 14 software* (trial version). The responses were categorized into nine thematic areas, initially coded through a systematic review of the interview transcripts.

These codes were subsequently grouped into subthemes, which were identified based on their frequency and recurrence across multiple participants.

This study was approved by the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy of Iași, through Decision No. 135/23.01.2022.

RESULTS

A total of 14 lawyers participated in our study, 10 of whom were men and 4 women. Regarding their professional experience, 5 lawyers had less than 10 years of practice, 3 had between 11 and 15 years, while 6 had over 15 years of experience.

Out of the nine major themes identified through the analysis of the conducted interviews, this article focuses on participants' perspectives regarding physicians' attitudes throughout the process of reviewing and resolving medical malpractice complaints. Within this thematic category, five subthemes were extracted from the participants' responses, most of which reflected the perception of a predominantly negative attitude among medical professionals.

1. Denial and Lack of Accountability

Some respondents perceived that physi-

cians tend either to categorically deny any possibility of wrongdoing or attempt to shift responsibility onto others.

"The physician continuously rejected the accusations, without even attempting to engage in a dialogue to resolve the conflictual situation." (Participant A12)

2. Non-cooperation

Another perception expressed by the interviewed lawyers was that physicians often refuse to engage in the resolution process and instead adopt a collective defensive stance. This attitude may lead to litigation, which ultimately has negative consequences for both parties involved.

"The doctor isolates himself, doesn't respond to anything, refuses to communicate with anyone, and allows the institution to speak on his behalf. Inevitably, the case ends up in court, where things can become extremely complicated." (Participant A2)

3. Formal Attitude

Some participants described a formal, procedural attitude on the part of physicians and medical institutions-one that prioritizes strict adherence to protocols. Compliance with procedural rules is an essential component of any legal process. When legal norms are disregarded, sanctions may be imposed on the responsible parties. This procedural compliance is seen as a dual obligation, applying equally to both the complainant and the defendant.

"You receive a response on time; no one accuses you of suing a prominent physician. At least on a formal, statutory level, impartiality is maintained." (Participant A3)

4. Aggressive Attitude

Some lawyers reported having perceived the attitude of physicians or their legal representatives as overtly aggressive.

"The doctor's lawyer came to the mediation session and almost verbally assaulted my client. We were all present, and she told my client, 'You, shameless woman, you're faking illness just to get medical leave" (Participant A14)

5. Delay and Concealment of the Truth

Several respondents observed that the conduct of medical personnel sometimes approached the boundaries of legality, potentially obstructing the course of justice. While the right to defense includes the accused party's ability to invoke the right to remain silent, such rights are not absolute. In cases where evidence is destroyed or altered, legal mechanisms exist to ensure accountability.

"In other instances, the hospital supporting the accused doctor offered illegitimate assistance. 'Oh, you didn't fill out the medical chart properly? Let's fix that now.' And they start tampering with the patient's records, forgetting that the patient had obtained a copy a year earlier… which only leads them into deeper legal trouble." (Participant A6)

DISCUSSION

The interviewed lawyers generally perceived the attitude of medical professionals during the resolution process of malpractice complaints as negative. In a study conducted in the United States in 2000, it was found that 50% of the physicians surveyed believed they bore no responsibility for the harm claimed by the complainant. In other words, respondents stated that they had made no error (6). Other studies investigating physicians' attitudes during malpractice complaint procedures have focused on the emotional experiences of healthcare professionals, identifying reactions such as shock,

fear, anger, anxiety, and frustration (7).

1. Denial and Lack of Accountability

In line with the opinions expressed during our interviews, both the lawyers' testimonies and the existing literature emphasize that medical malpractice proceedings are subject to significant debate in many countries worldwide (8). Stressful emotional events play a substantial role in the vulnerability of physicians involved in malpractice complaints (7). A related form of avoidance of responsibility identified in the literature is the practice of defensive medicine, whereby physicians refuse to treat certain patients (9) due to fear of potential malpractice claims.

2. Non-cooperation

The issue of non-cooperation was repeatedly highlighted by the lawyers interviewed for this study. According to the literature, such behavior is common among physicians. Many justify their reluctance to share information based on a paradoxical fear that anything disclosed could later be used against them during malpractice proceedings (10). Furthermore, studies have noted that non-cooperation may stem from a reluctance among some doctors to critique the professional conduct of their colleagues (11).

The statements made by our interview participants are thus corroborated by existing research. Physicians tend to believe that their professional accountability should be framed differently from that asserted by legal professionals. This fundamental disagreement fosters non-cooperative behavior, ultimately undermining the resolution process of malpractice complaints (6). It is also worth noting that this attitude may manifest not only during legal proceedings but also throughout the broader physician-patient relationship (12).

3. Formal Attitude

The lawyers interviewed in our study stated that physicians tended to adopt a formal attitude during the process of resolving malpractice complaints, with a strong emphasis on procedural compliance. In line with academic literature, healthcare professionals often adopt a closed and hierarchical communication style, as they believe such an approach shields them from liability in cases of medical malpractice (13).

Moreover, the formal demeanor exhibited by physicians, as discussed in the scholarly literature, is frequently shaped by the inherent formalism of legal accountability mechanisms concerning unlawful acts (14).

4. Aggressive Attitude

According to the opinions expressed by the interviewed lawyers, physicians displayed an aggressive attitude during the resolution process of malpractice complaints, despite the fact that the scholarly literature advises against such behavior (15). In a study identified in the literature, among the emotions reported by physician's subject to malpractice claims were irritability and indignation (5); however, no reference was made to overt aggression.

5. Delay and Concealment of the Truth

With regard to the lawyers' claims concerning delays and the concealment of the truth, the academic literature suggests that the current medical culture tends to discourage disclosure (16). This tendency is largely attributed to prevailing professional pressures within the medical field (17). The concealment of truth by physicians is also addressed from the perspective of medical ethics, where such behavior is sometimes justified by the intention

to avoid causing anxiety in patients or creating confusion due to the complexity of the information that must be communicated (18).

Moreover, scholarly literature refers to a phenomenon known as the "conspiracy of silence" (19), which occurs when physicians refrain from disclosing information about medical errors. This behavior-characterized by postponement and non-disclosure-may also be the unintended consequence of the way certain legal norms are formulated. Ambiguities in legal interpretation may inadvertently encourage physicians to remain silent, thereby influencing the resolution process of complaints submitted by patients (20).

CONCLUSIONS

Our study highlighted that lawyers tend to hold a predominantly negative perception of physicians' attitudes during the process of resolving medical malpractice complaints. The analysis we conducted revealed a lack of openness and cooperation on the part of physicians, manifested in various ways depending on the specific case.

The shortcomings of the current legal framework do little to encourage physicians to adopt a different approach. Procedures related to medical malpractice liability are often complex and burdensome, placing considerable pressure on healthcare professionals.

Our findings suggest the need for a mechanism that benefits both patients and physicians-one that fosters a more transparent and constructive approach from medical professionals in professional liability proceedings. Such a mechanism would facilitate the resolution of malpractice complaints in a more efficient manner, while minimizing the psychological and procedural impact on all parties involved.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding.

INVESTIGATION OF JOB SATISFACTION AMONG PHARMACISTS IN IAȘI COUNTY, ROMANIA: A QUANTITATIVE ANALYSIS (Abstract) **Aim**: Assessment of pharmacists' satisfaction with employers, working conditions, productivity, and their level of engagement in organizational activities. **Materials and methods**: The questionnaire, designed by academic staff of the Faculty of Pharmacy in collaboration with practicing pharmacists and pharmacy managers, comprised 23 questions with either open-ended or pre-formulated responses. It was completed by licensed pharmacists employed at various pharmaceutical units, both in public institutions and private ones, in Iași County. The questionnaire was administered online via a digital survey platform and in printed form to facilitate completion by pharmacists. **Results**: According to the obtained data, we found that the degree of agreement of the respondents regarding the level of job satisfaction is quite high (over 80%). A good communication in the pharmacy was indicated by 83.3% of the respondents, but 46% of the pharmacists consider that they are not remunerated at the desired level for the additional work performed, which may put the organization at risk in terms of workforce. Only 40% of respondents are satisfied with their choice of the pharmacist profession, which reflects the fact that there may be improvements regarding the possibility of increasing job satisfaction. **Conclusions**: Effective managerial communication is crucial for optimizing organizational structures and processes, adapting to dynamic markets and employee needs, and an annual internal communication audit could significantly enhance engagement and satisfaction within pharmaceutical units. **Keywords**: SATISFACTION, PHARMACIST, QUESTIONNAIRE, COMMUNICATION, MANAGEMENT, PATIENT.

INTRODUCTION

It is known that the medical-pharmaceutical field includes professions that rely heavily on communication, being one of the most relevant indicators of medical competence. The motivation for choosing this topic lies in the importance that must be given to the social side, the interaction between employees in the medical-pharmaceutical field. Studies in recent years show that good communication between employees can have a beneficial impact on the patient's health, as well as on increasing the degree of patient safety and satisfaction. However, education in Romanian Medical and Pharmaceutical Universities places too little emphasis on communication, and students/residents do not benefit from training in this regard (1-4).

The need for communication is obvious and necessary, as are the patients' demands to receive much better structured information. In this regard, it is important for medical personnel to practice more the

process of communication and relationships both among themselves and with patients. This involves knowledge, the ability to obtain information, and interpersonal relationship capacity (5-7).

The process of providing health care services must be in accordance with the patient's requirements. Achieving such a goal involves identifying all the connections between healthcare personnel and beneficiaries of medical services. Unfortunately, the environment in which the pharmaceutical and medical act is carried out is not always conducive to communication. The causes are numerous and include: lack of time, overcrowding, cultural differences, anxiety on the part of medical and pharmaceutical personnel and patients, fear of conflict and complaints, unrealistic expectations (8).

On the other side, employee satisfaction is the level of satisfaction that team members have with the roles they fulfill within the company, the activity they carry out, but also the satisfaction with certain professional relationships found in the organization (9-11). If you know how to increase or maintain employee satisfaction at a high level, organizational development can take place in the long term.

In this paper, we focused on job satisfaction of pharmacists in pharmaceutical units. In order to provide a broader perspective on the current state of the relationship between members of a pharmaceutical organization, we analyzed the factors that are considered important in the development of the communication process.

MATERIALS AND METHODS

We have created a questionnaire, through which we can observe the satisfaction of pharmacists with the employer, with working conditions, as well as the productivity and degree of involvement of pharmacists in organizational activities. A high degree of satisfaction of employees (internal customers of the organization) directly determines a high level of satisfaction from patients/consumers (external customers of the organization) (12-17).

The prospective cross-sectional study has as its research method a questionnaire-type survey carried out among pharmacists in community pharmacies in our geographical area, which was carried out over a period of 3 months (January-March 2025). This study was carried out in two phases: the development and validation of the questionnaire, and the evaluation of level satisfaction of the pharmacists. The time required to answer the questionnaire items was approximately 10 min. The questionnaire, designed by academic staff of the Faculty of Pharmacy in collaboration with practicing pharmacists and pharmacy managers, comprised 23 questions with either open-ended or pre-formulated responses. It was completed by licensed pharmacists employed in various pharmaceutical units, both in public and private institutions, in Iași County. The questionnaire was administered online via a digital survey platform and in printed form to facilitate completion by pharmacists (18-24).

Participants did not receive any material compensation for their participation in the research. The questions were designed to give us a comprehensive picture of pharmacists' job satisfaction. A total of 150 pharmacists of different ages, genders and training levels completed the questionnaire, all of whom completed the questionnaire were thus considered eligible. The results were analyzed and statistically interpreted. It was imperative to anonymized the collected data and adequately protect the identity of the subjects. Personal information was separated from the questionnaire responses to ensure confidentiality.

Subjects were thoroughly informed about the purpose of the study, how their responses would be used, who would have access to the data, and the duration of data retention. Additionally, explicit consent was obtained from participants for the collection and use of their data, with special emphasis on sensitive data. The entire study was conducted in accordance with the principles set forth in the Declaration of Helsinki, Law No. 190/2018, and Law No. 506/2004 regarding the processing of personal data and the protection of privacy in the electronic communications sector.

RESULTS

General characterization of the group. The study group is mainly composed of pharmacists who work in open-circuit pharmacies (82.7%) and who are permanently employed full-time (87.3%). The majority are pharmacists without additional specializations (71.3%), with over 6 years of experience in the same pharmacy (51.3%). About 64.6% of pharmacists have over 6 years of experience in the profession and three quarters of them (72.7%) have previously completed questionnaires about job satisfaction (tab. I).

TABLE I.
General characteristics of the study group

Question		n	%
1. Do you work in a pharmacy?	Closed-circuit	26	17.3
	Open-circuit	124	82.7
2. Do you work under contract in a pharmacy?	Full-time fixed-term	2	1.3
	Full-time permanent	131	87.3
	Part-time fixed-term	2	1.3
	Part-time permanent	6	4.0
	Temporary/Seasonal	9	6.0
3. Your position in the pharmacy is:	Pharmacist	107	71.3
	Pharmacist with a Ph.D.	3	2.0
	Primary pharmacist	3	2.0
	Resident pharmacist	13	8.7
	Specialist pharmacist	24	16.0
4. I have been working in this pharmacy for:	Less than 1 year	23	15.3
	1-5 years	50	33.4
	Over 6 years	77	51.3
5. My experience as a pharmacist is:	Less than 1 year	12	8.0
	1-5 years	41	27.3
	6-10 years	47	31.3
	Over 11 years	50	33.3
6. This is the first time I have completed a questionnaire about job satisfaction as a pharmacist:	No	109	72.7
	Yes	41	27.3
Total		150	100.0

The general analysis of the responses. This analysis shows that the degree of agreement of the respondents regarding the level of job satisfaction is quite high. The highest percentages of agreement with the proposed questions (over 80%) refer to the work schedule, with which 89.3% of the respondents agree, to the observance of the

rules imposed by the pharmacy superiors, with which 87.3% of the respondents also agree, and to the good communication in the pharmacy, indicated by 83.3% of the respondents. Over 70% of the respondents consider that they have good relations with the rest of the pharmacy staff, the tasks in the pharmacy are well explained to them, the mistakes they make are discussed and analyzed, they feel respected by their colleagues and the pharmaceutical unit is oriented towards the good of the patients. In contrast, pharmacists tend to be dissatisfied with the fact that they have not been promoted in the pharmacy where they work, 44% of them mentioning this aspect, and that the remuneration they receive is not equivalent to the work done (46% of respondents noted this aspect). Only 40% of respondents were rewarded for additional work in the pharmacy. The general degree of satisfaction of respondents with the profession of pharmacists is not very high, however only 40% of respondents are generally satisfied with the career choice made, 35.3% expressed their disagreement and a quarter (24.7%) are neutral on this subject (tab. II).

TABLE II.

Questionnaire responses-general results

Question	Agree		Disagree		Neutral		Total	
	n	%	n	%	n	%	n	%
7. I am satisfied with the profession of pharmacist that I perform.	92	61.3	36	24.0	22	14.7	150	100.0
8. My superiors appreciate my work in the pharmacy.	100	66.7	24	16.0	26	17.3	150	100.0
9. I consider that I have good relations with the rest of the pharmacy staff.	110	73.3	24	16.0	16	10.7	150	100.0
10. I have an adequate work schedule in the pharmacy where I work.	134	89.3	3	2.0	13	8.7	150	100.0
11. Communication in the pharmacy is good.	125	83.3	12	8.0	13	8.7	150	100.0
12. The tasks in the pharmacy are well explained.	110	73.3	24	16.0	16	10.7	150	100.0
13. I am periodically evaluated in the pharmacy.	98	65.3	22	14.7	30	20.0	150	100.0

21. I feel respected at the pharmacy by the patients.	99	66.0	12	8.0	39	26.0	150	100.0
22. I am rewarded for the additional work in pharmacy.	60	40.0	36	24.0	54	36.0	150	100.0
23. Overall, I am satisfied with the chosen profession of pharmacist.	60	40.0	53	35.3	37	24.7	150	100.0

Comparative study by type of pharmacy. In general, there are no statistically significant differences between pharmacists' responses regarding the degree of professional satisfaction in open-circuit pharmacies compared to closed-circuit ones. The degree of agreement differs by less than 5% between the responses in the case of items 7 and 15, and the only item for which statistically significantly different responses were recorded between the 2 categories of professionals was item 12, 75% of pharmacists working in open-circuit pharmacies consider that the tasks in the pharmacy are well explained to them compared to only 65.4% of those working in closed-circuit pharmacies. Of these, 7.7% consider that the tasks in the pharmacy are not properly explained to them and 26.9% are neutral, while in the case of open-circuit pharmacies only 7.3% are neutral, the remaining 17.7% considering that the tasks in the pharmacy are not properly explained to them. More than three-quarters of pharmacists working in closed-circuit pharmacies agree with the statements made in items 9, 10, 17, 18 and 20. Less than half agree with the statements made in items 16, 19, 22 and 23. Similarly, more than three quarters of pharmacists working in open-circuit pharmacies agree with the statements made in items 10, 11, 12, 17, 18 and 20, while less than half agree with the statements made in items 16, 19, 22 and 23. Regarding item 23, the general level of satisfaction with the chosen profession, it is relatively low, only 30.8% of pharmacists working in closed-circuit pharmacies are satisfied with their chosen profession, as are 41.9% of those working in open-circuit pharmacies, and the share of pharmacists dissatisfied with their chosen profession is 46.2% of those working in closed-circuit pharmacies, almost half, compared to only 33.1% of those working in open-circuit pharmacies, one third (tab. III).

The degree of satisfaction of pharmacists working in open-circuit pharmacies. We investigated in this subgroup of 124 pharmacists working in open-circuit pharmacies their degree of job satisfaction.

General characteristics of the subgroup. The vast majority of pharmacists in this category are permanent full-time employees (87.1%), depending on the pharmacist (69.4%) and have over 5 years of experience in the profession (61.3%) and over 5 years in the same pharmacy (50.0%) (tab. IV).

TABLE IV.
General characteristics of the investigated subgroup

Question		n	%
2. Do you work under contract in a pharmacy?	Full-time fixed-term	2	1.6
	Full-time permanent	108	87.1
	Part-time fixed-term	2	1.6
	Part-time permanent	4	3.2
	Temporary/Seasonal	8	6.5
3. Your position in the pharmacy is:	Pharmacist	86	69.4
	Pharmacist with a Ph.D.	2	1.6
	Primary pharmacist	2	1.6
	Resident pharmacist	12	9.7
	Specialist pharmacist	22	17.7
4. I have been working in this pharmacy for:	Less than 1 year	20	16.1
	1-5 years	42	33.9
	Over 6 years	62	50.0
5. My experience as a pharmacist is:	Less than 1 year	11	8.9
	1-5 years	37	29.8
	6-10 years	36	29.0
	Over 11 years	40	32.3
6. This is the first time I have completed a questionnaire about job satisfaction as a pharmacist:	No	92	74.2
	Yes	32	25.8
Total		124	100.0

Comparative study by position in pharmacy. In a first stage, we investigated the degree of professional satisfaction compared to the current position in pharmacy, which differentiates pharmacists without specializations from those with primary and possibly Ph.D. degrees, specialists or residents. In general, no statistically significant differences were found between these 4 categories of professionals in terms of the degree of professional satisfaction. Three quarters of primary or Ph.D. pharmacists (75%) are satisfied with the profession, compared to, for example, only half (50%) of specialist pharmacists. Resident and specialist pharmacists feel the most appreciated by their superiors (more than three quarters of them). Specialist pharmacists also consider that they have the best professional relations with the rest of the pharmacy staff (77.3%), as do those without specialization (74.4%). The vast majority of pharmacists are satisfied with their working hours and also with the communication in the pharmacy, which seems to be slightly more deficient only in the case of primary or Ph.D. pharmacists, of whom 25% are not satisfied with this aspect. The vast majority of specialist pharmacists (86.4%) consider that the tasks in the pharmacy are well explained to them, compared to only 66.7% of residents. On the other hand, almost all residents (91.7%) consider that they are periodically evaluated in the pharmacy, compared to just over half of the other categories of pharmacists. The vast majority of specialist pharmacists (81.8%) also consider that the pharmacy in which they work is oriented towards the benefit of patients, unlike about half of the other categories of pharmacists, a difference that is at the limit of statistical significance. All primary or

Ph.D. pharmacists feel appreciated in the pharmacy, compared to only 33.3% of resident pharmacists. Half of primary or Ph.D. pharmacists were promoted, compared to a third of residents and only 4.5% of specialist pharmacists, a discrepancy that also lies at the threshold of statistical significance. Three quarters of pharmacists, regardless of their professional position, believe that the mistakes they make at work are discussed appropriately and all resident pharmacists, like primary or Ph.D. pharmacists, believe that the rules imposed by superiors are respected. 75% of primary or Ph.D. pharmacists believe that the remuneration they receive is proportional to the work performed, compared to only 18.2% of specialist pharmacists and about half of the others in the other 2 categories, a difference that is also important and located near the threshold of statistical significance. As expected, all primary or Ph.D. pharmacists feel respected by their colleagues, as do 3/4 of the other categories of pharmacists. About 3/4 of pharmacists also feel respected by patients, most of them being resident pharmacists, of whom 83.3% feel respected by patients compared to only 66.3% of pharmacists without additional specialization. Only a quarter of primary or Ph.D. pharmacists believe that they are rewarded for the additional work they do in pharmacy, compared to 58.3% of resident pharmacists. In terms of overall satisfaction, three quarters of primary or Ph.D. pharmacists feel satisfied with their chosen profession, as do half of residents and 40% of specialist or non-specialized pharmacists (tab. V).

TABLE V.

Questionnaire responses by position in pharmacy

Question		Your position in the pharmacy is:								Pearson Chi-squared
		Pharmacist		Primary pharmacist / with Ph.D.		Resident pharmacist		Specialist pharmacist

Comparative study based on seniority at the pharmacy where they currently work. As expected, pharmacists with over 6 years of experience at the pharmacy where they currently work are the most satisfied with their profession (62.9%), although almost 60% of the other categories of pharmacists are also satisfied with their profession. The most appreciated by their superiors are pharmacists with seniority at the pharmacy where they currently work between 1 and 5 years (76.2% of them) and the least appreciated by their superiors are pharmacists with seniority less than 1 year, respectively 60% of them. Regardless of seniority, three quarters of pharmacists consider that they have good relations with their colleagues and almost all consider that the working hours are adequate and also that communication in the pharmacy is good. Also, 3/4 of pharmacists, regardless of seniority, consider that the service tasks are well explained and about 65% consider that they are evaluated periodically. 90% of pharmacists with less than one year of experience at the pharmacy where they currently work believe that the pharmacy is oriented towards the benefit of the patient, compared to only 65% of those with more experience at that pharmacy. The degree of appreciation in the pharmacy is similar for all categories of pharmacists, and 40% of those with less than one year of experience at that pharmacy have been recently promoted, compared to only 1/4 of the others. 85% of pharmacists with less than one year of experience at that pharmacy believe that the errors they make are dis-

cussed in the pharmacy, compared to only 69% of those with between 1 and 5 years of experience. The vast majority believe that the rules imposed by superiors are respected and just over half of pharmacists with between 1 and 5 years of experience at the pharmacy where they currently work believe that the remuneration received is equivalent to the work performed (54.8%), compared to only 1/4 of those with less than one year of experience. Pharmacists with less than one year of experience at the pharmacy where they currently work feel the least respected, with only 60% of them considering themselves respected by their colleagues and patients (55%). On the other hand, 60% of them consider themselves rewarded for the extra work they do, compared to about 38% of pharmacists with more experience. Half of pharmacists with less than one year of experience at the pharmacy where they currently work are generally satisfied with their chosen profession, compared to just over a third of those with between 1 and 5 years of experience at the pharmacy where they currently work (35.7%) and 43.5% of those with more than 6 years of experience (tab. VI).

Comparative study according to seniority in the profession of pharmacist. Finally, we conducted the same study according to the general seniority in the profession of the pharmacists interviewed. In this case, no statistically significant differences were found between the categories of pharmacists interviewed. The level of satisfaction with the pharmacist profession is the lowest among pharmacists with seniority between 1 and 5 years (56.8%), being high over 60% among the other categories of pharmacists. Pharmacists with seniority between 1 and 5 years, on the other hand, feel the most appreciated by their superiors (73%), compared to only 54.5% of pharmacists with seniority under one year. On the other hand, almost all of this category (90.9%) consider that they have good working relationships with the rest of the pharmacy staff, compared to only 66.7% of pharmacists with seniority between 6 and 10 years. All pharmacists with less than one year of experience consider that their working hours are adequate and that the level of communication in the pharmacy is good, as do the vast majority of others. The highest degree of disagreement with these 2 statements was found among pharmacists with between 1 and 5 years of experience. Over

80% of pharmacists with less than one year or more than 11 years of experience consider that their job tasks are well explained to them, compared to about 70% of those with between 1 and 10 years of experience. Only 57.5% of pharmacists with more than 11 years of experience consider that they are evaluated periodically, compared to, for example, 72.7% of those with less than one year of experience. Of these, the majority consider that the pharmacy is oriented towards the benefit of patients (90.9%), while only 65% of those with more than 6 years of experience have the same opinion. The most appreciated are pharmacists with over 11 years of experience (72.5%), but those who were promoted are those with less than a year of experience (45.5%). Those promoted less often are pharmacists with between 6 and 10 years of experience (16.7%). Almost all pharmacists with less than a year of experience believe that mistakes at work are discussed in the pharmacy (90.9%), compared to only 63.9% of pharmacists with between 6 and 10 years of experience who share the same opinion. The vast majority of pharmacists, regardless of experience, believe that the rules imposed by superiors are respected. Only 18.2% of pharmacists with less than a year of experience believe that the remuneration received is proportional to the work done, compared to over 40% of pharmacists with more experience. Also, pharmacists with more experience feel more respected by their colleagues than younger ones. 80% of pharmacists with over 11 years of experience also feel respected by patients. On the other hand, only half of those with 6 to 10 years of experience or less than a year of experience feel respected by patients. Almost three-quarters of pharmacists with less than a year of experience believe that they are rewarded for the extra work they do in the pharmacy (72.7%), compared to just over a third of those with 1 to 10 years of experience and 45% of those with over 11 years of experience. Satisfaction with their chosen profession is, however, admitted by about a third of pharmacists with up to 5 years of experience and by about 45% of those with over 6 years of experience. About a quarter of pharmacists, regardless of experience, are neutral regarding this statement and about a third are not satisfied with their chosen profession (tab. VII).

DISCUSSION

In 2023, a total of 18,241 pharmacists were licensed for independent practice in Romania, distributed across 8100 officially recognized community pharmacies spread throughout the country's 41 counties. The average number of pharmacists per county is approximately 450. Of these, the 150 pharmacist respondents of our study, representing 30% of officially employed pharmacists, constitute a significant proportion. Notably, in Iași, these 30% of pharmacists report a job satisfaction rate of only 40%, indicating substantial issues in a context where over 70% of them are deeply committed to the pharmaceutical practice and prioritize patient satisfaction over their own. This situation highlights the need to reevaluate working conditions and employment policies to enhance professional satisfaction among pharmacists.

This study aimed to raise awareness of the need for knowledge and continuous improvement of pharmacist communication skills, in all areas of pharmaceutical practice, in order to provide adequate counseling to patients, but also at the organizational level. We found international comparisons in specialized studies. For example, in Vietnam, hospital pharmacists reported 80.4% overall satisfaction, notably higher than Ethiopia (approximately 53%) and Malaysia (52%) (25, 26). Also, community pharmacists from New Zealand (NZ) felt their environment was conducive to safe care (57%) and had sufficient staffing (45%), while pharmacists from Canada are less satisfied (47%, respectively 32%) (27). Global early-career pharmacists (92 countries) found that workplace climate, training opportunities, workload, autonomy, and remuneration significantly influenced job satisfaction (28). Our study revealed that about 40% of pharmacists have positive overall satisfaction, with strong perceptions of team collaboration and communication, but lower scores in remuneration and promotion.

In Vietnam, working conditions were the strongest predictor of satisfaction, followed by leadership and benefits (25). In NZ and Canada, pharmacists reported inadequate time for breaks and tasks; dissatisfaction and psychological distress remained high (27). Swedish pharmacists reported high workloads but maintained strong satisfaction, possibly due to good continuing professional development (29). Our study highlights positive responses regarding schedule, task clarity, and communication, suggesting decent working conditions-though pay and promotion lag behind, thus reflecting trends from Europe.

In Ethiopia and Saudi Arabia, over 80% of pharmacists were dissatisfied with salary (26). In Iraq, pharmacists were relatively satisfied with income compared to developed countries (30). Reddit discussions indicate high pay/respect for pharmacists in Switzerland, Australia, UK, and Canada (31). Our study showed that 39.3% pharmacists believe salary matches work, with 46% dissatisfied, mirroring trends in Ethiopia and Saudi Arabia.

Ethiopian and Zimbabwean pharmacists cited lack of promotion and training as major dissatisfaction causes (26). Early-career pharmacists globally emphasized training and autonomy as key to satisfaction. In Sweden, career satisfaction was tied to access to continuing professional development (29). In our study only about 25% of pharmacists feel promoted, many lack regular evaluations echoing global

concerns around career stagnation and professional growth.

In Vietnam, the leadership and colleague relationships were significant satisfaction factors (25). Global studies reinforce the importance of work climate, autonomy, and recognition (28). NZ pharmacists also complained about time pressure, but valued environment with good staffing (27). In our study we found highly positive results on peer respect (75%), supervisor appreciation (66.7%), and communication (83.3%) align with leadership/work climate being core satisfaction drivers.

CONCLUSIONS

Based on the obtained results we can draw a series of conclusions and recommendations.

Clear career development pathways should be established, allowing pharmacists to specialize or advance professionally through defined criteria and opportunities. More experienced pharmacists should be encouraged to mentor newer colleagues, creating a culture of knowledge sharing and professional support. A transparent promotion system is needed, including specific benchmarks for advancement and internal job mobility. Management should explore the root causes of dissatisfaction by organizing confidential interviews, focus groups, or feedback sessions, and regular, anonymous job satisfaction surveys should be introduced to make continuous improvements.

To maintain strong team cohesion, regular team-building sessions, communication workshops should be scheduled and peer recognition practices should be encouraged. An annual internal communication audit could significantly enhance engagement and satisfaction within pharmaceutical units.

Work schedules should remain flexible and tailored to pharmacists needs and loyalty programs or milestone rewards implemented to acknowledge long-term employees. All extra hours worked or additional responsibilities should be appropriately rewarded.

A review of the current remuneration system is needed to ensure salaries that reflect the actual responsibilities and workload of pharmacists. Performance-based bonuses or alternative rewards, flexible days off, or training sponsorship should be considered to boost motivation.

In light of the research results, we consider useful that pharmacists should be empowered to take on more advisory roles, offering personalized guidance to patients to reinforce the pharmacy's patient-centered mission.

VALIDATION AND ADAPTATION TO THE ROMANIAN LANGUAGE AND POPULATION OF THE EBBCAM SCALE OF PERCEIVED COMPETENCE IN THE FACE OF DEATH, IN NURSING AND MEDICAL STUDENTS (Abstract): We carried out the translation, validation and cultural adaptation in Romanian language of the EBBCAM Questionnaire for the measurement of Perceived Death Competence in Medical and Nursing students. **Materials and methods:** 117 medical and nursing students of the Faculty of Medicine, Grigore T. Popa University of Medicine and Pharmacy Iasi. **Results:** The Romanian translation of the Bugen Brief Bugen Coping Competence in the Face of Death (EBBCAM) questionnaire, which is a multidimensional instrument consisting of 16 items, was administered. Subsequently, a Confirmatory Factor Analysis was performed in order to verify the validity of the measurement model. Both the study of the reliability of the responses (f1: .902; f2: .824; f3: .882 y f4: .828) and the Confirmatory Factor Analysis showed that the four-factor model had an adequate fit. (NNFI: .882; CFI: .920; IFI: .825 y RMSEA: .117). **Conclusions:** The Bugen Brief Competence in the Face of Death (EBBCAM) scale is a suitable instrument for the measurement of Perceived Competence in the Face of Death in Romanian-speaking students of Health Sciences (Medicine and Nursery). **Keywords:** DEATH COMPETENCE, VALIDATION, SCALE, ATTITUDES TOWARD DEATH, MEDICAL OR NURSING STUDENTS.

INTRODUCTION

The research shows how many health care professionals and health science students have difficulties in dealing with death, both their own and that of the patients they are taking care for (1, 2). In this sense, inappropriate management of one's own emotions, as well as poor self-knowledge (Bermejo, 2011) will influence the attitudes we adopt towards our patients, especially if they are at the final stage of their lives (3).

Any medical or nursing professional will sooner or later face death. It does not matter the service or area in which they work. From primary care in health centers or specialty

centers where elderly people and others suffering from degenerative diseases and terminal processes are attended, as well as in nursing homes and in any hospital unit, such as Palliative Care Units, Intensive Care Units, Internal Medicine Units, but also in Gynecology, Otorhinolaryngology or Ophthalmology Units, to name a few, where death may seem to be absent.

Perceived competence can be defined as the perception that one is capable of interacting effectively with the environment (4). The study of competence in the face of death is, therefore, fundamental for the effective performance of the tasks and processes involved in end-of-life care (5-7). For this purpose, the translation, validation and cultural adaptation in Romanian language of the EBBCAM Questionnaire for the measurement of Perceived Death Competence in Medical and Nursing students has been carried out.

MATERIALS AND METHODS

Measurement instrument. The EBBCAM scale (Bugen Brief Scale of Competence in the Face of Death) is an adaptation of the EBAM scale made by Medrano (2017; 2020) (8, 9), it is composed of 16 statements that evaluate 4 dimensions, to each dimension belong some of these statements. The EBBCAM is composed of the following dimensions or factors:

f1: Assistance and communication;

f2: Post-mortem care;

f3: Self confidence

f4: Management of own fear.

The reliability for the present scale in each of its dimensions respectively is: .787, .766, .814, .702 respectively.

Methodology

1. To carry out the adaptation process (translation and content validity), the scale was first translated from Spanish into Romanian by three Romanian nationals, third- and fourth-year students of the Nursing Degree at the Catholic University of Valencia (Spain), and then corrected by a non-professional in the health sciences, a native speaker of Romanian and Spanish. Subsequently, the translated scale was revised by an official translator in Romania (Iasi).

2. Data collection was implemented through an online questionnaire developed by one of the authors (VP). The time to complete the questionnaires was estimated at less than 15 minutes.

3. To study the psychometric properties of the scale, a study of its validity and reliability was carried out. For this purpose, a structural equation model was specified, estimated and evaluated, and internal consistency estimates were calculated.

The equation model carried out, confirmatory factor analysis (CFA), is characterized by representing the causal processes under study by means of a series of equations, and these structural equations can be modelled pictorially to conceptualize more clearly the theory studied (10).

This procedure is appropriate when, as in this case, the researcher has prior knowledge about the relationships between the observable variables (items), in this case, the original structure proposed by the authors.

The CFA tested for the EBBCAM Questionnaire specified a structure of four correlated factors (Companionship and communication, Post-mortem care, Self-confidence and Self-fear management), which depart from Medrano's original model (8, 9) and which would explain the 16 items of the instrument (fig. 1).

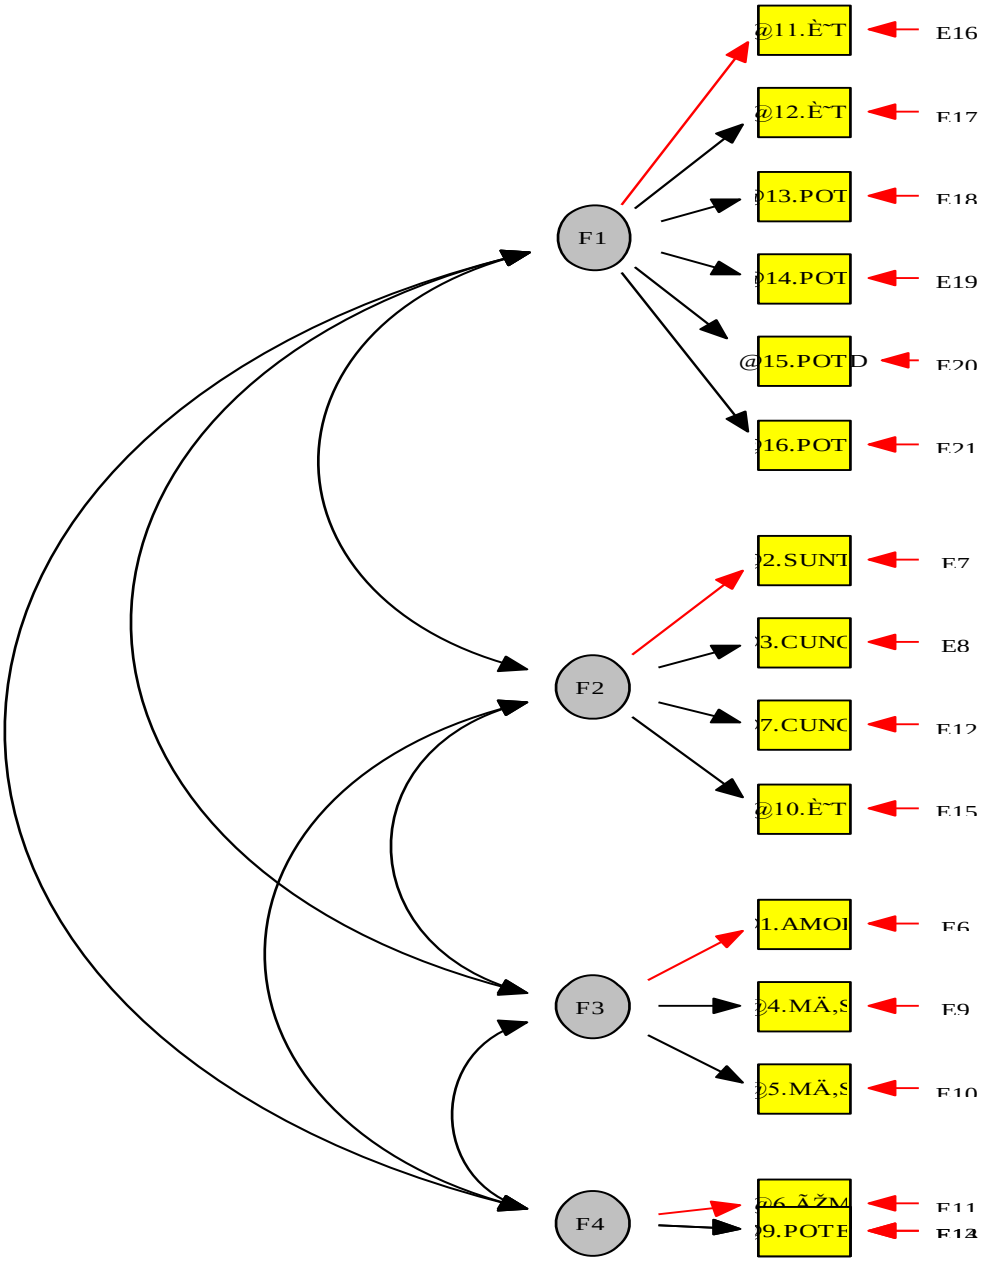

Fig. 1. Proposed confirmatory factor analysis of the EBBCAM Questionnaire

RESULTS

There is a high representation of the 5th and 4th courses, medium in the third and first grades and low in the second grade. Also, there is a high female participation and a low participation of male students.

Both groups (medicine and nursing) are optimally represented, although with a higher participation of medical students (tab. I).

TABLE I.
Basic sample data

N=117		
Average age		22.2 (SD: 3.01)
Age range		18-43
		N (%)
Sex	Male	17 (14.5)
	Female	100(85.5)
Marital Status	Single	108 (92.3)
	Married	9 (7.7)
Specialty	Medical	78 (66.6)
	Nursing	39 (33.3)
Year of study	**1º**: 12; **2º**: 6; **3º**: 15; **4º**: 58; **5º**: 25	

Table II shows that the four factors analyzed have high reliability (tab. II).

The confirmatory factor analysis shows an adequate fit to the theoretical dimensions from the original EBBCAM scale in Spanish (tab. III).

The confirmatory factor analysis shows an adequate fit to the theoretical dimensions from the original EBBCAM scale in Spanish (tab. III).

TABLE II.
Internal consistency for theoretical factors

	f1	**f2**	**f3**	**f4**
α	.902	.824	.882	.828

This section may be divided by subheadings. It should provide a concise and precise description of the experimental results, their interpretation, as well as the experimental conclusions that can be drawn.

DISCUSSION

Based on recommendations in the litera-

ture (11, 12), the fit of the models to the data was assessed using various criteria, such as the chi-square (χ^2) statistic (13). This statistic, however, has been widely criticized for its sensitivity to sample size, the magnitude of correlations, and violations of multivariate normality assumptions, which has led researchers to rely on complementary indices of model fit. Consequently, several alternative fit indices have been developed to provide a more robust and nuanced evaluation of how well a model represents the observed data. Among these, the Comparative Fit Index (CFI) and the Root Mean Square Error of Approximation (RMSEA), both employed in the present study, are among the most widely accepted and frequently reported indicators in structural equation modeling. The CFI compares the fit of the hypothesized model with that of a null model that assumes zero covariances among the observed variables, thereby reflecting the relative improvement in fit achieved by the proposed model. It ranges from 0 to 1, with higher values indicating better model fit. Values above .90 are generally interpreted as acceptable, whereas values above .95 are considered indicative of excellent fit (9, 14). In this sense, the CFI provides a standardized measure of how well the specified relationships among variables reproduce the observed covariance structure.

The RMSEA, in contrast, evaluates the degree of approximation error of the model in the population rather than in the sample. It estimates how well the model would fit the population covariance matrix if it were available, thereby accounting for model complexity and degrees of freedom. Values of zero indicate a perfect fit, while values below .08 are typically interpreted as reflecting an adequate fit to the data (15, 16). Lower RMSEA values therefore suggest that the discrepancies between the hypothesized model and the observed data are small and within acceptable limits. Together, the CFI and RMSEA offer complementary perspectives on model fit, capturing both relative and absolute aspects of model adequacy. Using both indices provides a more balanced and rigorous evaluation than relying on a single statistic alone.

To evaluate the reliability of the scales, Cronbach's alpha was computed for each of the subscales. This coefficient is the most widely used index of internal consistency and reflects the extent to which the items within a scale measure the same underlying construct. Values between .70 and .79 are generally considered to indicate moderate reliability, whereas values of .80 or higher are interpreted as reflecting high reliability (17). In the present analyses, the reliability estimates not only met these accepted standards but also exceeded those reported in the original Medrano version of the instrument (9). This improvement suggests that the current adaptation demonstrates enhanced internal consistency and psychometric robustness in the studied sample.

CONCLUSIONS

The data show a good psychometric fit and high reliability, making the Romanian version of the Bugen Brief Death Competence Scale a reliable and valid instrument for application in the Romanian population. This scale is easy and quick to apply and offers useful data in specific areas related to the analyzed construct.

DEMOGRAPHIC AND CLINICAL FEATURES WITH SURGICAL CONSIDERATIONS IN ADULT CRANIOPHARYNGIOMAS: A ROMANIAN NEUROSURGICAL CENTER EXPERIENCE (Abstract): Craniopharyngiomas (CPs) are rare benign epithelial tumors of the sellar-suprasellar region that remain surgically challenging. **Aim**: To evaluate the clinical, imaging, pathological and surgical aspects of CPs diagnosed in adult patients as such previous analyses are rare. **Materials and methods:** We performed a retrospective study that included adult patients (≥18 years) with surgical treated and pathologically confirmed CP between January 2016 and December 2021. Eligible cases were analyzed regarding demographic data, clinical presentation, and surgical approach. **Results:** Eleven adult patients were included (mean age 46.6 ± 12.6 years), with a slight female predominance (54.5%). Two peaks in patients' age were noted: one in the fifth decade of life (40- to 49-year-olds) and another in the seventh decade of life (60- to 69-year-olds). Visual disturbances were the most frequent presenting symptom (81.8%), but headache (54.5%), endocrine disfunctions (36.36%), and neurocognitive symptoms (27.3%) were also identified. Open craniotomy was performed in 72.7% of cases, while extended endoscopic endonasal approach was realized in the rest of the cases. Subtotal resection was achieved in 63.6% of all cases. **Conclusions:** The findings of our study align with published data, while highlighting specific diagnostic peculiarities in Romanian adult patients with craniopharyngiomas. **Keywords:** CRANIOPHARYNGIOMA; ADULT PATIENTS; VISUAL DISTURBANCES; SURGICAL APPROACH.

INTRODUCTION

Craniopharyngiomas CPs) are rare intracranial epithelial tumors that develop from remnants of Rathke's pouch due to errors occurring in the process of differentiation during embryogenesis (1).

Even though, from a histologically point of view, CP was first described more than a century and a half ago and the first successful surgical resection of such a tumor was performed at the beginning of the 20th century (2,3), this entity is still considered "a challenging tumor of the sella" (4) due to its proximity to vital neurovascular structures and the difficulties in surgical interventions when surgeons try to reach the tumor.

Although both 2021 WHO 5th edition of Classification of CNS tumors (5) and the

latest 2025 WHO 5th edition Classification of Endocrine Tumors (6) assign grade 1 malignancy to craniopharyngioma, this tumor is associated with varied clinical manifestations, elevated recurrence, long-term postsurgical comorbidities, but also with a high risk of mortality (7-10).

In the United States, the incidence of pathologic-confirmed CP was 0.16 per 100,000 persons. This tumor has a bimodal distribution, with two peaks, one in childhood (5- to 9-year-olds) and another in adults (55 - to 69-year-olds) (1).

In adults, these tumors account for 1-3% of all primary intracranial tumors (11), but it is believed that the incidence could increase in the coming period due to widespread use of cranio-cerebral computed tomography (CT) and Magnetic Resonance Imaging (MRI) whenever a neurological or endocrinological symptoms appear (12).

In recent years, comprehensive studies on the demographic, clinical, imaging, pathological and surgical aspects of CPs are mostly review-type (11, 13-15), and those based on case series are quite rare, often analyzing a very small number of patients (16, 17). In addition, reports on CPs identified in children (12, 18, 19) are more numerous than those dedicated to craniopharyngioma diagnosed in adults (20) or studies that include both pediatric and adult patients (21).

Considering that some differences in tumor biology, clinical presentation and functional outcomes have been reported depending on age (22), in the present study, we performed a retrospective analysis of CPs diagnosed in adult patients and treated in the Prof. Dr. N. Oblu Clinical Emergency Hospital in Iași, Romania, which is a tertiary care center with a reference area of approximately 5 million inhabitants. The aim of this study was to evaluate the clinical, imaging, pathological and surgical aspects of CPs diagnosed and treated in this health institution in adult patients and to compare these data with data from similar studies in the literature, as such previous analyses are rare. Such data may provide a new perspective on this disease in adults, providing useful information for future treatments.

MATERIALS AND METHODS

The study was approved by the Ethic Committee of Prof. Dr. N. Oblu Emergency Clinical Hospital, Iași, Romania (No. 1333/ January 1st, 2023), as a quality control study. Informed consent was obtained from all patients included in this study.

A retrospective study of patients who underwent surgical intervention for CP for a period of 6 years (January 1, 2016 and December 31, 2021) in the Department of Neurosurgery, Prof. Dr. N. Oblu Emergency Clinical Hospital, Iași, Romania, was performed.

The inclusion criteria were as follows: (1) adult patients (aged 18 years and older) admitted in any Neurosurgery Departments during the study period within the Hospital and having pathologically confirmed diagnosis of a CP; (2) all clinical, imaging, pathological and surgical data available.

The exclusion criteria were as follows: (1) Pediatric patients (aged less than 18 years) admitted in any Neurosurgery Departments during the study period within the Hospital and having pathologically confirmed diagnosis of a CP; (2) absence of informed consent; (3) unavailability of relevant clinical data; (4) previous resection or radiotherapy for their CP.

Over the analyzed period, searching in

the hospital database identified 18 patients with pathologically confirmed CP. Seven patients were excluded after meticulous scrutiny based on exclusion criteria. Finally, 11 patients were found eligible for further analysis.

For these 11 patients, data were collected from medical records and included: patients' demographic data (gender and age), presenting symptoms at admission, tumor location identified on magnetic resonance imaging (MRI), as well as type of the surgery (transcranial approach *vs.* endonasal approach) and extent of tumor resection (total *vs.* subtotal).

The information was collected using a data collection sheet. Due to the small sample size, all correlations were analyzed descriptively; some values were reported as a number, or as a number and percentage, while others as a mean ± SD value or as a median value.

RESULTS

In 6 years, 11 adult patients with CP met the inclusion criteria for the present study. Their mean age at diagnosis was 46.6 ± 12.6 years (range 23-64), with a median age of 46 years. There was a slight female predominance (54.5%), the female-to-male ratio being 1.2: 1.

In the present series, the presence of two peaks in the identification of craniopharyngioma is noted: one in the fifth decade of life (40- to 49-year-olds) and another in the seventh decade of life (60- to 69-year-olds (fig. 1).

Because symptom reporting was heterogeneous, all of them were coded into standardized categories based on narrative descriptions (tab. I). Visual disturbances were the predominant presenting symptom, observed in 81.8% of all cases, including blindness, visual field defects, and decreased visual acuity.

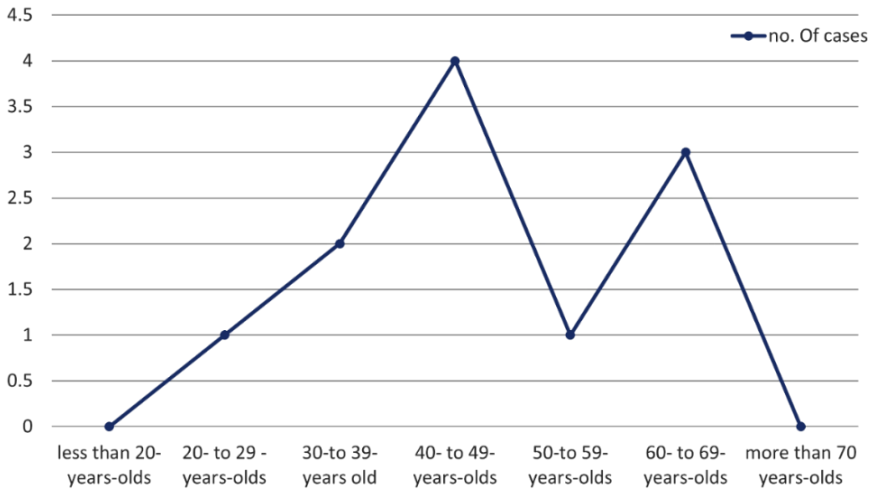

Fig. 1. Craniopharyngiomas distribution along the life decades in the study cohort.

Headache was reported by 54.5% of all patients, while endocrine disfunction was identified in 36.36% of all cases, diabetes insipidus being documented in 18.2% of all

cases. 27.3% of all cases exhibited neurocognitive symptoms such as confusion, or somnolence.

MRI tumor evaluation for CP location (tab. II) demonstrated a predominant suprasellar involvement, either isolated or combined with sellar extension (5/11 cases; 45.45%). Development of a CP in peri mesencephalic cistern was observed in a minority of cases (9.1%). Also, pure third ventricle (V3) location was rare (9.1%). Suprasellar tumor development with V3 extension was identified in 18.2% of cases. Prepontine tumor extension was recorded in 9.1% of cases. Wide tumor extension (prepontine and into the Sylvian fissure) was also identified in only 9.1% of cases.

Surgical resection (tab. III) was performed through open craniotomy in 8 cases (72.7%) (fig. 2) and by extended endoscopic endonasal approach in 3 cases (27.3%) (fig. 3). Gross total resection was achieved in 4 cases (36.4%) subtotal resection in 7 cases (63.6%).

TABLE I.

Clinical characteristics of the study cohort

MAIN PRESENTING SYMPTOMS	n	(%)
Visual disturbances (blindness, visual field defects, decreased visual acuity)	9	81.8%
Headache	6	54.5%
Endocrine disfunction	4	36.36%
• Diabetes insipidus	2	18.2%
• Pituitary FSH and LH deficiency	1	9.1%
• Pituitary GH and ACTH deficiency	1	9.1%
Neurocognitive symptoms (confusion, somnolence)	3	27.3%

TABLE II.

Craniopharyngioma locations identified on MRI scans

TUMOR LOCATION (MRI)	n	%
Exclusive development in suprasellar region	2	18.2%
Exclusive development in peri mesencephalic cistern	1	9.1%
Exclusive development in the V3	1	9.1%
Sellar and suprasellar development	3	27.3%
Suprasellar development with V3 extension	2	18.2%
Suprasellar development with prepontine extension	1	9.1%
Sellar and suprasellar development, with prepontine and Sylvian fissure extensions	1	9.1%

TABLE III.

Surgical management of patients with craniopharyngiomas, including type of surgical approach and extent of tumor resection in the present series (n = 11).

SURGICAL VARIABLE	n	(%)
Types of surgical approach		
• Extended endoscopic endonasal approach	3	27.3%
• Open craniotomy	8	72.7%
○ Trans callosal / trans ventricular approach	4	36.4%
○ Fronto-temporal/ pteryonal approach	4	36.4%
Extent of tumor resection		
• Gross total resection (macroscopic)	4	36.4%
• Subtotal resection	7	63.6%

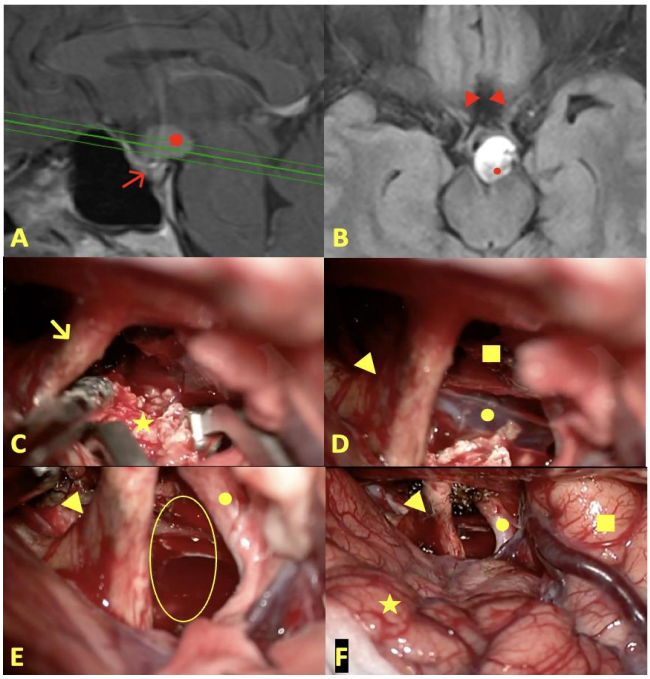

Fig 2. A) and B) images - preoperative MRI showing a suprasellar lesion with contrast enhancement (circle), the normal pituitary gland (arrow) and the optic nerves (arrow head) and a calcified portion (circle). C) To F) images: intraoperative pteryonal approach - showing on C) - the optic nerve (arrow) and the calcified portion of the lesion (star), D) - optic nerve and the optic chiasm (arrowhead), the pituitary gland (square) and the Lilliquist membrane (circle), E) - intraoperative aspect after tumoral resection showing the optic nerve (arrow head) right carotid artery (circle) and the optical-carotid window (oval); F) - same image at lower magnification.

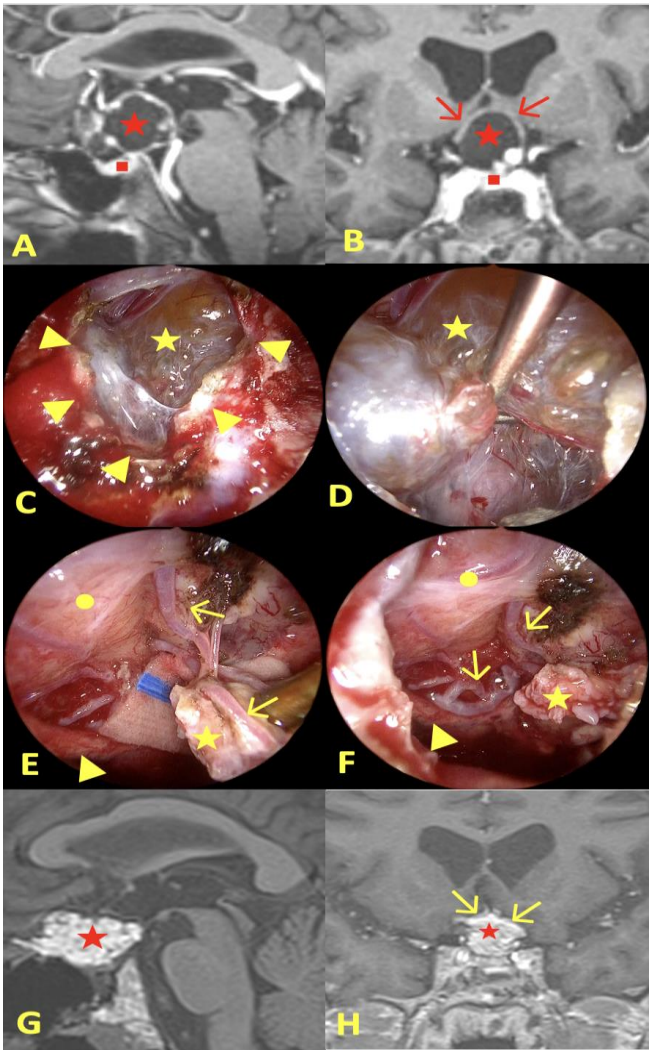

Fig 3. A and B MRI with contrast enhancement showing a cystic suprasellar lesion (star) the superior displacement of the optic chiasm (arrows) and the normal pituitary gland at the level of the sella (square). C-F intraoperative images (extended endoscopic transsphenoidal approach): C - at the level of the sphenoid sinus showing the opening of the dura (arrow heads) with exposing of the lesion (star), D - closer view of the tumor, E - intraoperative aspect after partial resection showing the tumor capsule (star) with close adhesion to the A2 segment of anterior cerebral artery (ACA) (arrow), the right optic nerve (arrow head), and the right basal frontal lobe (circle), F - final step of the resection showing the right optic nerve (arrowhead), the particular anatomic conformation (fenestration) of the anterior communicating complex (arrow) and a small tumor capsule remnant on the A2 segment of left ACA (star). G-H postoperative MRI showing the reconstruction of the skull base with fat plug (star), and the anatomic integrity of the anterior communicating complex (arrows).

DISCUSSION

Craniopharyngiomas diagnosis and management remain challenging because of their complex anatomy, heterogeneous imaging appearance, and frequent overlap with other sellar and suprasellar lesions (23).

The literature reports that CP has a bimodal age distribution with two peaks: one at age 5-14 years and the second at age 45-74 years (24), which may suggest the influence of certain underlying biological or environmental factors that contribute to the age-related incidence of the disease (25).

The present cohort, made up of adult patients (≥ 18 years old), included predominantly middle-aged adults (mean age 46.6 years) with a slight female predominance. Our data are different from those reported by others who found a slightly male predilection (26) or, more recently, no gender predilection (11). The demographic profile of the present cohort is also different from those reporting only one peak of CP incidence in adult patients, either in age group 40-44 years (26, 27) or 45-74 years (24). We found a small shift from the reported data because we identified two separate peaks (at 40-to 49 years-old and at 60- to 69-years-old). These new data can signify a change in tumor biology or a particularity for our study group.

From a clinical perspective, CP presentation in adults is often insidious with many and various symptoms that can be difficult for patients as well as for clinicians to identify early (16). Because CPs develop in close proximity to vital structures (optic pathways, hypothalamus, thalamus, brain stem), their clinical spectrum includes endocrine, visual, and neurological impairment, as well as hypothalamic syndrome and increased intracranial pressure syndrome (23, 28).

The high prevalence of visual disturbances in our cohort (81.8%) closely mirrors reported rates ranging from 60% to over 84% in adult and mixed populations (10, 27) reflecting the frequent suprasellar extension and optic chiasm compression characteristic of CPs (25). However, visual symptoms are common to multiple other sellar region tumors and therefore lack discriminatory value.

The identification of visual disturbances in a high percentage in the present series also reflects the fact that the patients presented late to the neurosurgeon when CP already developed as a bulky tumor, with wide extension into neighboring structures, including the optic chiasm and hypothalamus.

Increased intracranial pressure due to voluminous tumor itself or to the hydrocephalus resulting from compression of V3 determine headache, which can occur in 35% - 68% of cases (10, 27). In the present study, the identified value for headache falls between these values, which demonstrates that even though the cohort was small, the data obtained are correct and align with those reported by authors from other countries. Also, in the present cohort, the frequent association with headache and hydrocephalus further emphasizes the mass effect exerted by these lesions, particularly in tumors with intraventricular extension.

Compression of the pituitary gland by any lesion cause anterior pituitary dysfunction with variable deficiencies of Growth Hormone (GH), gonadotropins [Follicle-Stimulating Hormone (FSH) and Luteinizing Hormone (LH)], Adrenocorticotropic Hormone (ACTH), or Thyroid Stimulating Hormone (TSH). The literature reported that the most common deficiency encoun-

tered in CPs are those of GH (86% of cases) (27), gonadotropins (40%), ACTH (25%), and TSH (25%) (25). Compression of the pituitary stalk and/or hypothalamus, determine hypothalamic-pituitary dysfunction with vasopressin deficiency manifesting as diabetes insipidus that appear in 17-38% of cases (25, 27). In the present cohort, adult patients with CPs also presented at admission some endocrine dysfunction, but the percentages are much lower than those reported by other authors, probably because they were not properly investigated preoperatively given the diagnostic error upon admission to the hospital.

Cognitive deficits (such as impaired memory, attention, and reduced processing speed), or sleep disorders (somnolence) appear in 17% to 71.5% of CP patients, especially in those with voluminous tumors that compress the hypothalamus (16, 29). The values obtain in the present series align with these reported percentages.

CPs have exceedingly a heterogeneous topography because these tumors may arise anywhere on the path of embryonic cell migration (7). Most CPs are located in the sellar and parasellar regions (23), an aspect also identified in the present series.

CPs can extend in all the directions: superior, inferior, lateral, anterior and posterior. MRI plays a pivotal role in evaluating the complex patterns of extension of CPs and their relationship with adjacent neurovascular structures.

These tumors may extend superiorly from the suprasellar region with compression of the third or lateral ventricles, laterally into parasellar regions and cavernous sinuses, anteriorly toward the frontal lobes with displacement of the anterior cerebral arteries, or posteriorly into the peri mesencephalic cisterns, brainstem, and cerebellar spaces. Inferior extension to the sellar region, paranasal sinuses and nasopharynx may also be observed.

Accurate identification of these extension patterns is essential for surgical planning, guiding the choice between total and subtotal resection, and for differentiating craniopharyngiomas from other extensive skull-base lesions (30).

The tumor can also develop in the V3, either within the neural tissue of the infundibulum and tuber cinereum, which are components of V3, or strictly in V3, originating in its subependymal area (31). However, the incidence of purely intraventricular CPs accounts for 0.5 to 11% of all cases, as we also found in the present study. Most important is the fact that CPs located in V3 posse surgical challenges because of the complex and vital surrounding structures, including the hypothalamus, infundibulum, optic pathways, limbic system, and nearby vasculature (32).

Ectopic locations of CP have also been identified in adults, but they are extremely rare, published only as isolated case reports. As far as we know, CP location in the prepontine cistern, a situation in which there is no sellar involvement or endocrine dysfunction (33), in the temporal lobe with no connection to the craniopharyngeal duct (34), the nasopharynx, the posterior fossa, and the spine (7), or orbit (35) have been reported.

Although limited in terms of the small number of cases, two of these ectopic locations of the CP were also identified in the present series, namely in V3 and the peri mesencephalic cistern, which, prior to the pathological diagnoses, determined an erroneous imaging diagnosis and a real surgical challenge.

Surgical management remains the cor-

nerstone of CP treatment. The choice of the type of surgical approach is adapted to each individual case, but also in correlation with the equipment of each hospital and the presence of at least one neurosurgeon specialized in such surgical interventions. The goal of a quality surgical intervention is to achieve a radical resection while minimizing damage to the surrounding vital neurovascular structures, especially the hypothalamus (21).

In the present series, surgical treatment was performed predominantly through open craniotomy approaches, reflecting frequent large tumor extension into the surrounding neuroanatomical structures, while endoscopic endonasal surgery was reserved for selected midline lesions.

Recent literature has reported increasing use of endoscopic endonasal approaches in selected midline lesions; however, these approaches are generally reserved for tumors with favorable anatomy and limited lateral or ventricular extension, offering a direct midline corridor while minimizing brain retraction. Also, it has the advantage of a gross total resection ranging of up to 70% in some series (36, 37).

In the present study, due to the predominance of large tumors with adherence and large invasion into adjacent vital neural structures, the surgeon took the decision to make a subtotal resection in two thirds of cases in order to avoid postoperative morbidity. The introduction of the extended endonasal endoscopic approach and the existence of a well-trained neurosurgeon led to a reconsideration of this tactic in our hospital.

CONCLUSIONS

This study offers a detailed analysis of demographic, clinical, and surgical data showing their utility in the management decisions of patients with craniopharyngiomas. Overall, the present cohort shows strong concordance with published series, but also highlighted certain particularities that are probably related to the genetic pools of the patients studied and to the craniopharyngioma changing biology in the last years. We found out two peaks of the incidence of craniopharyngioma developing in adults, a slight predominance of affecting female patients, and some particular and rare locations of craniopharyngiomas, such as ventricle 3 and peri mesencephalic cisterns. The predominance of transcranial approaches in our cohort is comparable to many contemporary surgical series, particularly in craniopharyngiomas with large tumor volume and suprasellar or intraventricular extension.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest.

FACTORS INFLUENCING THE LEVEL OF DEPRESSION AMONG FRESHMAN NURSING STUDENTS (Abstract): **Aim**: To identify the level of depression among nursing students and the factors that influence it. **Material and methods**: A group of 89 nursing students were included in the research. Socio-demographic data (age, sex, marital status, and experience as a nurse) and four instruments were used *(The Beck Depression Inventory, Eysenck Personality Inventory, The Maslach Burnout Inventory* and *The Job Satisfaction Scale)* to identify the level of depression, burnout, the personality traits, job satisfaction scores and the relationship between the considered variables. Data have been processed using SPSS 17. **Results and discussion**: Almost 20% of first-year nursing students have symptoms of depression, ranging from mild to severe. Significant statistical correlations were identified between depression and age, experience as a nurse, emotional exhaustion, introversion, emotional instability and job satisfaction. **Conclusions**: Melancholic individuals are more prone to depression than other temperaments. The more emotionally exhausted individuals are, the higher their chances are of developing depression. Emotional instability is increasing the risks of depression. **Keywords:** NURSING STUDENTS, DEPRESSION, EMOTIONAL EXHAUSTION, PERSONALITY TRAITS, JOB SATISFACTION.

The academic years are usually very stressful for all medical students. Firstly, the distress level is determined by the large and diverse amount of disciplines and by the continuous assessment. Secondly, psychological distress is due to the interaction with the patients during their practice stages. Thirdly, the transition from adolescence to maturity and the changes in their personal lives also have consequences on their psychological well-being.

Apart from burnout, depression is one of the most important psychological problems experienced by nursing students during their academic years. The scientific literature provides data for the general population of students, about 33%. Regarding the presence of depressive symptoms among nursing students, the data presented are different, depending on the country: 52.4% in Greece (1), 22.9% in China (2), 30.2% in Brazil (3), 30.5% in Denmark and 43% in Saudi Arabia (4, 5).

Studies have also pointed out that re-

ports for depressive symptoms among medical students are higher compared to the general population, even before students begin their medical education (4).

Identifying and providing knowledge about depression and burnout among healthcare professionals is an important aspect of medical education. Professionals in the medical field are exposed to higher risks of depression and professional exhaustion, and their negative impact on work and successful results has been proved by the researches in the field: higher rates of errors and of difficulties in maintaining good relationships with patients or colleagues and low rates of job-related satisfaction (6, 7).

The aim of the present study is to evaluate the level of depression among first-year nursing students and to identify its relationship with personality traits, burnout, job satisfaction and socio-demographic variables. The article is part of an extended research focusing on psychological problems related to socio-demographic aspects and personality traits among freshman students from nursing studies.

MATERIAL AND METHODS

A group of 89 freshman students from the nursing specialty took part in the research. A fill-in paper recording socio-demographic data and 4 instruments were provided, after the students were informed about the goal of the research and the confidentiality of personal data.

Socio-demographic data like age, sex (male, female), environment (urban/rural), marital status (single, in a partnership), the number of children in the family of origin (singleton/siblings), having children (yes/no) and length of experience as a nurse were recorded.

Four instruments were used for the research to evaluate depression and the relationship with burnout syndrome, personality traits and job-related satisfaction:

1. The level of depression was evaluated by *The Beck Depression Inventory* (BDI). The instrument has twenty-one items using a four-point scale ranging from 0 (symptom is not present) to 3 (symptom is very intense). Ratings from 0 to 13 are considered in the minimal range, 14 to 19 mild, 20 to 28 moderate, and 29 to 63 severe depression (8) The Cronbach alpha (.85) shows good internal consistency.

2. *Eysenck Personality Questionnaire* (EPQ) was used to assess participants' personality traits (9). This instrument with 57 items evaluates psychoticism, extraversion, neuroticism and social desirability. Combining scores for the two subscales, the four types of temperaments are identified (sanguine, melancholic, choleric and phlegmatic). Extroverts are usually outgoing, talkative, and in need of external stimulation, while introverts are overstimulated and excitable; they need peace and quiet to achieve a good level of performance. People high on neuroticism experience high levels of negative affect, such as depression and anxiety, while emotionally stable people are calm and don't experience negative affect unless they are faced with major stressors. Psychoticism is associated with aggression and with chances of having a psychotic episode and Lie/Social Desirability measures the extent to which respondents try to be socially desirable in their answers. The instrument has good internal consistency, with a Cronbach's alpha coefficient of 0.81.

3. The burnout syndrome was evaluated using *The Maslach Burnout Inventory* (MBI). The instrument contains three

scales which have nine, five and respectively eight items. MBI evaluates e*motional exhaustion* (referring to the feeling of being emotionally spent and fatigued by work), d*epersonalization* (describing coldness in responses towards the beneficiaries of one's work) and *personal achievement* (related to feelings of competence and achievement in working with other people). The higher scores on *emotional exhaustion* and depersonalization subscales are related to higher degrees of burnout and lower scores on the *personal achievement* subscale correspond to higher rates of burnout (10). For the three subscales we obtained the following Cronbach's alpha scores: .828, .591 and .829.

4. Because more than half of the students are working in the medical field, we have also wanted to evaluate the level of job-related satisfaction with *The Job Satisfaction Scale* (JSS). The instrument contains 4 subscales with a total of 32 items: *payment and promotions* (assessing someone's satisfaction with rewards like payment, promotion etc.), *management and interpersonal relationships* (the employee's satisfaction with the social setting, the relationships he/she has with colleagues/manager), *organization and communication* (the employee's satisfaction with work organization and the way work is performed) and the total score for the scale - *overall job satisfaction*-providing a total score for satisfaction with all aspects of the work (11). The Cronbach alpha scores for the subscales are: .77, .61 respectively .62 and for overall job satisfaction the score is .86.

The data were processed using *SPSS 17.0* for Windows. We used descriptive statistics to point out the results obtained for each instrument used (mean and standard deviation). For the comparative analysis we used one-way ANOVA and Independent Samples *t* Test. For the correlational analysis we used Pearson correlations and for the regression analysis we used multiple linear regression.

RESULTS AND DISCUSSION

Descriptive analysis

Socio-demographic data papers and scales to be filled in were distributed among first-year nursing students in a university in north-eastern Romania. A number of 89 fully filled-in questionnaires were returned in time. The students come from 6 counties from this region (Bacău, Botoșani, Iași, Neamț, Suceava, Vaslui). Socio-demographic data are presented in Table I.

The research focused on depression, temperamental traits, burnout and job satisfaction scores. The results obtained using the four instruments are presented in Table II.

Depression was evaluated for all participants. The analysis of scores proves that 9.5% of the participants have mild depression, 6.7% have moderate depression, and 2.2% have severe depression.

Regarding burnout subscales, it has been identified that 15.7% of students have high levels of emotional exhaustion, for the other two subscales the scores are low.

Eysenck scores focused on revealing introvert/extrovert traits and the emotional in/stability. The analysis of data proved that 42% of participants are introverts and 58% are extroverts, while 53.4% are emotionally stable and 46.6%, emotionally unstable. The temperamental categories are: 28.1% of students are sanguine, 25.8% are phlegmatic, 14.6% melancholic, and 31.5% choleric.

TABLE I
Socio-demographic data

Variables		N (%)
Gender	Male Female	8 (9) 81 (91)
Environment	Urban Rural	55 (62.50) 33 (37.50)
Age (25.52 ± 9.42)	Minimum age Maximum age	19 48
Relationship status	Single (single or divorced) In partnership (couple or married)	58 (65.2) 31 (34.8)
Children	Have children No children	19 (21.3) 70 (78.7%)
Experience as nurse	Yes No	24 (24.7) 65 (75.3)
Length of employment as a nurse (3.31 ± 6.52)	Minimum length Maximum length	1 year 26 years
Family of origin	Singleton Siblings	14 (15.7%) 75 (84.3)

TABLE II
Scores for BECK, Eysenck, JSS, MBI

Instruments	Scale/subscale	Mean ± Standard deviation
BECK		10.08 ± 8.70
EYSENCK	introversion - extraversion	11.43 ± 3.41
	stability - instability	12.34 ± 4.40
	social desirability	3.60 ± 1.82
MBI	emotional exhaustion	19.54 ± 10.08
	personal achievement	12.79 ± 8.56
	depersonalization	6.57 ± 5.41
JSS	payment and promotion	3.23 ± .70
	management-interpersonal relationships	4.05 ± .72
	organization-communication	4.28 ± .60
	overall satisfaction	3.80 ± .58

Correlational analyses

Pearson correlations were used for the investigated variables in the present study. A positive relation was identified between age and depression (meaning that the higher the age is, the higher the scores on depression are) and between the length of employment as a nurse and depression (the more nursing experience participants have, the higher they score on depression).

TABLE III

Results regarding correlations between depression and other variables

	Variables	Depression
SOCIO-DEMOGRAPHIC DATA	Age	**R = .256*, p = .019**
	Number of children	R = .036, p = .745
	Nurse experience	**R = .347*, p = .001**
EYSENCK	Introversion-extraversion	**R = -.271*, p = .013**
	Stability-instability	**R = .309**, p = .005**
MBI	Emotional exhaustion	**R = .362**, p = .002**
	Personal accomplishment	R= -.098, p = .417
	Depersonalization	R= -.145, p =.230
JSS	Payment-promotion	**R = -.257*, p = .032**
	Management-interpersonal relationships	**R= - .317**, p = 007**
	Organization-communication	**R = - .333**, p = .004**
	Overall job satisfaction	**R = - .354**, p = .003**

A negative correlation between introversion-extraversion and depression were identified, meaning that higher scores on this subscale of the *Eysenck Personality Questionnaire* correspond to lower levels of depression and a positive correlation appears to exist between the stability-instability subscale and depression. More exactly, the higher the scores on stability-instability, the higher the scores on depression; the lower the scores on stability-instability, the lower the scores on depression.

The relationship between depression and subscales of MBI was analyzed. Positive correlations were pointed between the *emotional exhaustion* subscale and depression, meaning that higher scores on *emotional exhaustion* are associated with higher scores on depression, while lower scores on *emotional exhaustion* are associated with lower scores on depression.

Negative correlations were identified between depressions and factors of job satisfaction (including the overall scores). The more satisfied participants were on *payment-promotion*, the lower they scored on depression. When considering the *management-interpersonal* relationships subdomain, the higher subjects scored on this variable, the lower their scores on depression. The more individuals were satisfied with the *organization-communication* aspect of job satisfaction, the less depressed they felt. Finally, the higher the score is for *overall job satisfaction*, the lower the depression value is. It is important to point that the results prove that depression affect all job-related aspects.

Comparative analysis

For the variables where we have three or more independent (unrelated) groups (temperament, burnout), we used the one-way analysis of variance (ANOVA) in order to establish if there are any statistically significant differences between the means of these groups. For the variables where we have two independent groups (nursing experience, presence of children, relationship status), we used the Independent Samples *t* Test. This is a parametric test comparing the means of two independent groups and determining if the means are significantly different.

The number of male students is too low to proceed with a comparative analysis, to analyze if there are some differences between men and women, considering this variable. Studies from the literature point out some higher scores for depression for female students, compared to males (12).

To determine whether the type of temperament has an influence on depression, we took into consideration the four known types: sanguine, phlegmatic, melancholic, and choleric. One-way ANOVA results (F (3.80), p = .005) show that there is a difference in depression among participants, according to their temperament. Multiple/post-hoc comparisons showed that sanguine individuals have lower scores on depression compared to melancholic individuals. Another difference that has emerged is that phlegmatic people have lower scores on depression compared to melancholic people. Finally, melancholic individuals have higher scores on depression compared to choleric individuals.

While the comparison between introverts and extroverts reveals no statistically significant differences (t [81] = 1.733, p = .087), the Independent Samples *t* Test shows that there is a difference between stable and unstable individuals on depression: t [81] = -2.134, p = .037. More specifically, stable individuals have lower scores on depression compared to unstable individuals.

For analyses concerning burnout subscales, we divided the variable into three groups on each of the three subscales: emotional exhaustion, personal achievement, and depersonalization. The results of one-way ANOVA showed that only emotional exhaustion influences depression (F (2.68) = 4.126, p = .020). Multiple/post-hoc comparisons showed that individuals with low scores on emotional exhaustion have lower scores on depression compared to those with high scores on emotional exhaustion.

For analyses concerning nursing experience, we divided the participants into two groups: no nursing experience and with nursing experience. The statistical analysis showed no differences in depression between participants with or without nursing experience (t [82] = -1.579, p = .129).

The results of the comparison between participants with and without children showed no differences concerning depression (t [82] =.013, p = .990).

When comparing single individuals with the ones involved in a relationship, the results of the Independent Samples *t* Test (t [82] = -.698, p = .487) showed no differences regarding the depression level between single students and those involved in a partnership. The analysis of results from the scientific literature provides different results about the scores for depression when it is about the marital status. The study of Sharokani et al. (13) mentioned that single students are more susceptible to higher rates of depression compared to married students. Contrary to these results, Bayram et al. (14) reported lower rates for single students.

Regression analysis

The table of correlations revealed the influence of some variables (age, nursing experience, introversion/extraversion, stability/instability, emotional exhaustion, payment-promotion, management interpersonal relationships, organization communication, and overall job satisfaction) on depression. To identify the most effective model for estimating the predictors for depression, we used multiple linear regression by the hierarchical method.

Of the 9 models in which the depression criterion was tested, the fifth model explains 30% of its variance. Among the 5 predictors of the model, only stability/

instability and emotional exhaustions are significant predictors of depression (p = .016, respectively p = .027), their effect on the criterion being positive (b = .613, beta = .277, respectively b = .253, beta = .266). Results are presented in Table IV.

TABLE IV
Regression analysis

	Model	Adjusted R^2	F	R^2 change
Step 1	Age	.063	5.041 (p =.029)	.079
Step 2	Age, nurse experience	.120	5.106 (p =.009)	.071
Step 3	Age, nurse experience, introversion/extraversion	.167	4.997 (p =004)	.059
Step 4	Age, nurse experience, introversion/extraversion, stability/instability	.247	5.928 (p =.000)	.089
Step 5	Age, nurse experience, introversion/extraversion, stability/instability, emotional exhaustion	.300	6.132 (p =.000)	.060
Step 6	Age, nurse experience, introversion/extraversion, stability/instability, emotional exhaustion, payment-promotion	.287	5.025 (p =.000)	.000
Step 7	Age, nurse experience, introversion/extraversion, stability/instability, emotional exhaustion, payment-promotion, management-interpersonal relationships	.303	4.731 (p =.000)	.026
Step 8	Age, nurse experience, introversion/extraversion, stability/instability, emotional exhaustion, payment-promotion, management-interpersonal relationships, organization-communication	.291	4.085 (p =.001)	.001
Step 9	Age, nurse experience, introversion/extraversion, stability/instability, emotional exhaustion, payment-promotion, management-interpersonal relationships, organization-communication, overall job satisfaction	.295	3.793 (p =.001)	.015

CONCLUSIONS

The research proves that almost 20% of first-year nursing students have symptoms of depression, ranging from mild to severe. The factors influencing the level of depression are temperament, emotional exhaustion and emotional stability. Melancholic individuals are more prone to depression than sanguine, choleric and phlegmatic individuals. The more emotionally exhausted individuals are, the higher their chances are of developing depression. Regarding emotional stability, we identified that unstable individuals present higher risks of developing depression. The results are important for both students and teachers, to be aware that personality traits and coping strategies are important for the personal and professional life.

NEWS

A NEW HYPOTHESIS OF THE AETIOLOGICAL FACTORS IN DENTINE HYPERSENSITIVITY

Dentine hypersensitivity is a relatively common dental complaint, derived from the exposure of dentine. A recent study of O'Toole and Bartlett analyzed 600 adults, with the mean age of 44, using a questionnaire that included data of the tooth hypersensitivity, acidic intake habits and toothbrushing habits. Results showed that the intake of the acidic drinks between meals, the habit of sipping, swishing or holding drinks in the mouth prior to swallowing, consuming fruit in more than 10 minutes at a single sitting, the use of a soft brush and the presence of severe erosive tooth wear were connected with dentine hypersensitivity. The authors concluded that the contact time of the acid inside the oral cavity might be a more important factor for the dentine hypersensitivity compared to frequency of the acid intake or frequency of toothbrushing. (O'Toole S, Bartlett D. The relationship between dentine hypersensitivity, dietary acid intake and erosive tooth wear. *J Dent*; 2017; Available from: http://dx.doi.org/10.1016/j.jdent.2017.10.002)

ETIOLOGICAL AND CLINICAL-PARACLINICAL IMPLICATIONS OF ACUTE ABDOMIMAL PAIN IN CHILDREN (Abstract): Abdominal pain is the most important symptom of digestive diseases in children, being one of the most frequent reasons for their coming to the general practitioner, pediatrician or emergency room. The etiological possibilities for abdominal pain are numerous and the condition is difficult to manage even in the best of clinical circumstances, but especially in children who cannot tell a precise history or locate the pain. In such circumstances, the most important role of the doctor is to distinguish between benign self-limiting conditions, and life-threatening diseases, which are true surgical emergencies. Thorough anamnesis and full physical exam of the child guides the diagnosis, and paraclinical tests targeted to the most common group of diseases depending on the child's age will lead in most cases to setting the positive diagnosis and thus allow the timely initiation of an adequate therapy, either medical, or surgical. This review aims to provide an update on the etiology and the main diagnostic methods of acute abdomen, helping discriminate between those patients who can be managed entirely in primary care, with recommendations based on the most currently accepted concepts in the management of acute abdomen in children. **Keywords**: ABDOMINAL PAIN, ACUTE ABDOMEN, CHILDREN.

The term "acute abdomen" designates any traumatic or non-traumatic condition with fast onset and digestive pain and symptoms, which requires urgent hospitalization in a surgical ward for monitoring and possibly surgical therapy, if necessary.

Abdominal pain is the third most common chief complaint in emergency departments and is a difficult condition to diagnosis even in the best of clinical circumstances, and especially in children who cannot tell a precise history or locate the pain (1). The etiological possibilities are numerous, but abdominal pain is the most important symptom of digestive diseases and it occurs in most abdominal conditions (involving the guts, the peritoneum, the vessels and nerves, the mesentery, the omentum). When the pain is very sharp, accompanied by other signs and symptoms, and especially when it occurs suddenly, the children are brought by their parents directly to the emergency room of the hospital (2). In this case, the most important role of the doctor is to distinguish between benign self-limiting conditions, such as acute viral

gastroenteritis, constipation or infant's abdominal colic, and life-threatening diseases, which are true surgical emergencies. This review aims to provide an update on the etiology and the main diagnostic methods of acute abdomen, helping discriminate between those patients who can be managed entirely in primary care, with recommendations based on the most currently accepted concepts in the management of acute abdomen in children.

Patient assessment and anamnesis

The process of making a triage decision always begins by reassurance that the child is clinically stable. After this, patient assessment should start with a thorough anamnesis about the child's age, personal medical history, possible history of physical injury or psychological trauma, presence or absence of appetite (for instance, a child who is hungry is less likely to have appendicitis), pain onset and chronic nature, and associated symptoms, and it should be followed by a detailed physical exam. The child's anamnesis and physical exam are essential for diagnosis setting and for choosing the right therapeutic approach, and especially for developing a relationship of trust between the doctor and the patient, and the family, considering the usually difficult circumstances of the exam (in the emergency room, while the child is in great pain and the family is deeply distressed). Anxiety increases even more when a possible surgical condition is suspected and it reaches its peak in the family when the surgeon comes. Therefore, it is extremely important for the surgeon performing the anamnesis to be infinitely patient and calm, and to allow the family and then the child (if he/she is older than 2-3 years) to tell what the problem is, while carefully observing the patient's movements when he/she undresses and is asked to lie on his/her back.

The **child's age** can provide important information. In neonates, congenital malrotation of the small bowel can result in volvulus, causing bowel obstruction with biliary, fecaloid or bloodstained vomiting. Hirschprung's disease is also a potential diagnosis in neonates that present with enterocolitis. In children aged between 2 months and 1 year, intussusception is the most common cause of bowel obstruction. Puberty may be the cause of vague abdominal pain in girls with the first menstruation. Just remember that in any girl of child-bearing age pregnancy should always be excluded. Also for adolescents, check for adnexal torsion in girls and testicular torsion in boys.

Pain onset may provide useful information. For example, a sharp sudden pain spreading quickly throughout the whole abdomen may be suggestive of gastrointestinal perforation, adnexal torsion or ruptured extra-uterine pregnancy in female adolescents. Extreme agitation of the patient suggests the involvement of an ischemic mechanism, the pain being stabbing, accompanied by paleness, reflex vomiting and perspiration (vagal signs), like in intussusception, volvulus or adnexal torsion. Any pain with insidious onset and increasing intensity may suggest an infectious (acute appendicitis, Meckel diverticulitis), obstructive (bowel obstruction) or neoplastic process. The pain onset seat, when it may be set, namely in children older than 5-6 years, may provide precious information: a pain starting in the epigastrium and then moving towards the right iliac fossa is suggestive of acute appendicitis, a pain in the right hypochondrium irra-

diating in the shoulder is specific to irritation of the diaphragm (sub phrenic abscesses after acute peritonitis for which surgery was recently performed) or to acute cholecystitis, a pain in the left iliac fossa and left hypochondrium is characteristic to enterocolitis, whereas a diffuse periumbilical pain is suggestive of intestinal parasites. When investigating abdominal pain, it is important to ask about pain elsewhere in the body as this can also give clues towards the cause of the disease (referred pain). Common examples are scapular pain due to biliary colic, shoulder pain due to blood or infection irritating the diaphragm (Kehrs sign: left shoulder tip pain is a classical symptom of a ruptured spleen).

The second most common symptom of acute abdomen is **vomiting**, which may be reflex, in case of ischemia or peritoneal irritation (acute volvulus, strangulated hernia, acute appendicitis), or may be the consequence of an obstruction, which is initially food-related and subsequently becomes bilious and then fecal. Impaired intestinal gas and feces transit, or, on the contrary, diarrhea (especially in small children) may both be signs of acute surgical abdomen.

Finding the cause of acute abdomen in children younger than 5 years is extremely difficult since the child is neither able to express the type or intensity of the pain, nor to locate it, since the ability to locate abdominal pain appears after the age of 4-5 years, with the maturity of the central nervous system. Sometimes, atypical and not very noisy symptoms, or even the absence of physical signs, are another impediment. For instance, a 2-year child with peritonitis may be simply lethargic, complaining of abdominal distention and diarrhea. Therefore, on the first exam, acute appendicitis is mistaken for something else in almost 100% of the patients up to 2 years of age and in 28-57% of the children below the age of 12 (3). The key to early diagnosis is a high level of clinical suspicion, based on the clinical experience of the first doctor examining the child. Given the difficulties encountered when assessing young children with abdominal pain, the ruptured appendix rate is much higher in children than in adults, ranging between 30 and 65% (4).

Clinical Assessment

Clinical assessment should be done using the systematic process of inspection, auscultation, palpation and percussion. Therefore, it will start by a general exam of the body, with special focus on the abdomen, to detect any abdomen rigidity or distention, skin rashes (Henoch-Sconlein purpura), postoperative scars, possible sings of injury (fig. 1). Palpation is used to detect any areas of guarding, tenderness or any masses and should start away from the area of tenderness. The abdomen should be palpated gently, while observing the patient's facial expression and respecting the little patient's hand that will push the doctor's hand away from the painful spot. Percussion is also a good way of assessing for peritonism and will elicit pain even if the patient has received strong analgesia. Abdomen percussion may reveal hyper sonority in case of pneumoperitoneum or dullness in case of fluid effusions, and auscultation may detect bowel sounds in case of bowel obstruction or abdominal silence in peritonitis or paralytic ileus. One must always ensure that the inguinal and scrotal areas are examined for strangulated hernias, testicular hydrocele in tension or acute scrotum syndrome.

Fig. 1. Sign of injury – bike handlebar blow – in a child with post-injury jejuna perforation

All physical exams for acute abdomen should end with a **rectal exam**, which may provide extremely important data: pain in the pouch of Douglas in case of appendicitis or peritonitis, palpation of an ovarian tumor or of an extra-uterine pregnancy; also, rectal exam may detect the presence of a fecalith or rectal polyp, may set a diagnosis of infant's intussusception in the presence of specific "red currant jelly" stool or "meat juice" bleeding (fig. 2).

Fig. 2. Rectorrhagia after rectal examination – in an infant with intussusception

However, rectal exam may induce severe discomfort, defined as major crying or screaming, in nearly one fourth of children presenting with possible appendicitis, and mild discomfort, defined as facial grimacing, was reported in another 37% (5). That is why the information gained from the rectal examination must be weighed against the potential of induced physical discomfort.

Paraclinical Assessment

Complete blood count and erythrocyte sedimentation rate, coagulation tests, biochemical exam, urine and stool tests are the routine laboratory tests that should be performed. For adolescent girls, pregnancy testing may also help narrow the differential diagnosis. The **blood count** and coagulation tests may reveal the presence of hemorrhagic anemia (in case of abdominal injury, for instance), abnormally high inflammatory test findings are suggestive of acute appendicitis or another infectious process, high amylase and lipase levels may point to acute pancreatitis. **Hematuria** is specific to a renal condition like lithiasis, but it may also occur in case of irritated ureter by an inflamed retrocecal or mesoceliac appendix. Diarrhea is specific to acute enterocolitis, yet it may also occur in the peritoneal irritation syndrome, whereas blood present in the stool may point, together with perineum and rectal examination, to anal fissures due to constipation, rectal polyp or intussusception (fig. 2).

Among the imaging tests, **ultrasound scanning** is usually the first method that is recommended due to its accessibility and non-invasive nature, as well as to its ability to contribute precious information for diagnosis setting and therapeutic approach. The ultrasound may reveal:

- the presence of free fluid in the peritoneal cavity – blood in case of spleen or liver injuries, gastric or intestinal fluid in

digestive perforations, reaction fluid or puss in acute appendicitis or peritonitis (6);

- the presence of inflamed aperistaltic cecal appendix, possibly with an inner appendicolith, with a diameter exceeding 6 mm in case of acute appendicitis;
- the presence of intraperitoneal abscesses – appendicular, subhepatic, peri splenic and pouch of Douglas abscesses;
- signs of acute cholecystitis – thickened gallbladder wall or small wall abscesses, pericholecystic abscess, gallbladder lithiasis;
- the presence of parenchymatous organ lesions in case of injury - hematoma or ruptured spleen, liver, kidney;
- diminished intestinal peristalsis, thickened-wall fluid-filled intestinal loops – for instance, in peritonitis or acute enterocolitis;
- distended intestinal loops, which are filled with fluid and air – in mechanical obstructions;
- specific "target-like" or "loop-in-loop" signs – in case of intussusception, in which case the ultrasound allows the real-time watching of loop disinvagination when air is blown in or a serum or contrast agent enema is performed (7);
- the presence of abdominal or retroperitoneal tumors;
- the state of the girls' inner genitalia, the presence of ovary cysts or pathological ovarian torsion – ovarian teratoma, hemorrhagic ovarian cyst (8);
- the state of the urinary system – hydronephrosis, kidney, ureter or gallbladder lithiasis, kidney or gallbladder tumors, full bladder.

If there is any suspicion of occlusive syndrome (hydroaeric levels revealed by abdominal X-ray), gastric or intestinal perforation (pneumoperitoneum) or ingestion of foreign bodies, a **thoracic-abdominal X-Ray** of the standing patient is recommended (fig. 3 and 4). Thoracic X-ray may reveal the presence of broken ribs, in case of injury, hydro or pneumothorax, or it may reveal basal pneumonia with symptoms such as occasionally sharp abdominal pain, vomiting, poor general condition resembling acute surgical abdomen.

Fig. 3. Occlusive syndrome – hydraeric levels

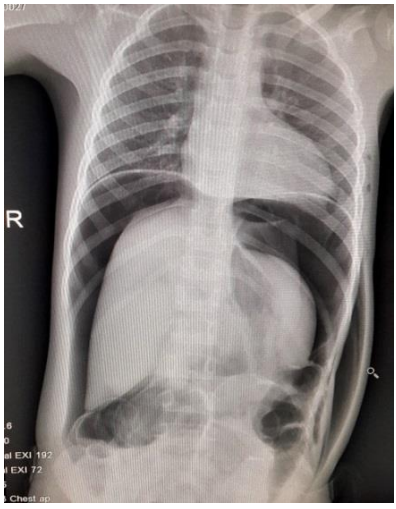

Fig. 4. Pneumoperitoneum – colic perforation

Due to the high radiation dose involved and to the need of young child sedation, **computed tomography** (CT) diagnosing acute abdomen in children should be recommended with caution, only when the children are obese, in case of uncertain diagnosis or when the ultrasound scan is inconclusive. However, CT is the preferred diagnosis setting method in case of abdominal injury, as it accurately reveals both solid organ lesions and possible cavity organ perforations. It is also recommended when assessing acute pancreatitis or intestinal inflammatory diseases, whereas in case of abdominal tumors nuclear magnetic resonance (NMR) is preferred, despite it being rarely accessible in the emergency room and despite the drawback of its requiring general anesthesia (9). Tests like angiography, upper or lower digestive endoscopy, paracentesis in case of fluid in the peritoneal cavity (which may reveal the presence of blood, intestinal fluid, pus, ascites fluid, urine) are more rarely used in children in the emergency room.

Laparoscopy has a special place among diagnosis setting exams, being used more and more often lately including in children, due to its many advantages: very small incisions, the possibility of probing the whole abdomen and of flushing it using physiological saline solution, the possibility of peritoneal fluid sampling or biopsy sampling for biological and pathological anatomy tests, and especially the possibility of solving the cause of acute abdomen (ovarian torsion solving and fixation or excision, appendectomy and peritoneal lavage, ileum perforation suture, peritoneal adhesion lysis, hernia reduction and hernia gap closing).

Causes of Acute Abdomen in Children

Here are the most common **medical** caused of acute abdomen in children: constipation, intestinal parasites, acute gastroenterocolitis, dyspepsia, allergy to cow milk proteins, esophagitis due to gastroesophageal reflux, irritable bowel syndrome, urinary tract infection and ureter colic, virus A hepatitis. Also, consider acute mesenteric lymphadenitis in children presenting after a viral illness or new onset diabetes presenting with abdominal cramps, which are associated with diabetic ketoacidosis. Acute gastroduodenitis, cholecystitis, acute idiopathic or toxic pancreatitis are causes of acute abdomen which usually require drug treatment, although they may sometimes get complicated and require surgery.

Recurrent abdominal pain is a prevalent disorder affecting 10% to 15% of school-age children (10, 11). In many cases, recurrent abdominal pain in children has psychogenic (**functional**) origins, without having a specific organic cause (infection, inflammation, tumor, obstruction). The big difficulty with recurrent abdominal pain is the fear of missing significant or serious underlying pathology. Table I gives a brief overview of how to differentiate functional from organic abdominal pain (12).

Psychogenic pain may be accompanied by symptoms such as anorexia, nausea, vertigo, cephalalgia, paleness, constipation and, more rarely, vomiting or diarrhea. Psychogenic pain occurs in sensitive overprotected children, with a family history of depression or anxiety, and it is associated with a series of stress factors like a history of frequent diseases, lactose or other hydrocarbon intolerance, drug administration, aerophagia, constipation, and especially with psychosocial factors like the death of

a parent or of another family member, arguments, divorce or separation from the family for other reasons, jealousy after the birth of a sibling, school or financial problems. Psychogenic abdominal pain is sometimes hard to diagnose, it is attributed to various organic conditions and treated with drugs. Drugs should not ordinarily be given because may aggravate the family's panic and the concept of the pain, creates an unnecessary dependency, and are almost always unrewarding. The treatment is useless unless the psychological cause is found and removed.

TABLE I.
Differentiating organic from functional abdominal pain

Clinical feature	Organic	Functional
Site of pain	Loin, suprapubic, right upper and lower quadrants	Central
Family history of abdominal pain, headache and depression	Less likely	More likely
Anxiety	Less likely	More likely
Headache	Less likely	More likely
Alarm symptoms	Persistent or significant vomiting, chronic diarrhea, fever, gastrointestinal blood loss	Less likely
Poor growth/weight gain	Yes	No
Abnormal full blood count, erythrocyte sedimentation rate or urinalysis	Yes	No

False acute abdomen (extra-abdominal pain causes) may be caused by: basal pneumonia, myocardial infarction, diabetic ketoacidosis, pericarditis, spine conditions, and central nervous system tumors.

The **surgical** causes may be grouped in four syndromes:

- The peritoneal irritation syndrome and acute peritonitic abdomen, respectively: acute appendicitis and appendicular peritonitis, more rarely primitive acute peritonitis, Meckel diverticulitis, perforated gastric ulcer in adolescents; in the specialty literature, the acute appendicitis is the most common cause of surgical acute abdomen in children, being diagnosed in 1-8% of the children coming to the emergency room complaining of abdominal pain (13, 14);
- Occlusive syndrome: intussusception, malrotation, inner hernia, intestinal obstructions due to adhesions or roundworms, strangulated inguinal hernia; intussusception is the most common cause of acute surgical abdomen in infants under the age of one, its incidence rate peaking between the age of 6 and 11 months (3);
- Hemorrhagic syndrome: intestinal polyposis, ruptured intestinal hemangioma, bleeding ulcer in Meckel's diverticulum;
- Visceral ischemia syndrome: enteromesenteric infarction (rare in children), normal or pathological ovarian torsion, gastric volvulus and intestinal volvulus, torsion of a pedicle abdominal tumor;
- Acute traumatic abdomen: abdominal injuries with ruptured solid organs or perforated cavity organs; as part of acute surgical abdomen, injuries have had an in-

creasingly higher occurrence rate due to the higher number of causing events, such as road accidents, aggressions, sporting events (fig. 1).

The etiological diagnosis may sometimes not be accurately set before the surgery, doctors only being able to determine the type of acute surgical abdomen that it belongs to. What is important is to decide whether surgery is required, as the procedure should be performed in due time, usually within a few hours, after a short hydro-electrolytic, acidic-basic rebalancing, abdominal decompression if necessary (naso-gastric drainage), antibiotic therapy or blood transfusions (on which the patient's life is sometimes dependent – for instance, in internal hemorrhage due to ruptured spleen or liver). Older literature recommended, in principal, not to administer analgesics to children with abdominal pain until setting the diagnosis or at least until the surgical examination, since the analgesics may conceal the progress of an acute surgical process. However, once the diagnosis is set and the therapeutic approach is decided on, ruling out any surgical cause, analgesics should be administered immediately. Recent research has proven that the use of analgesic drugs in children with abdominal pain does not increase the risk of diagnosis errors and it should therefore be administered immediately, even before the surgical exam (15).

DISCUSSION

Abdominal pain is one of the most common reasons for the children's coming to the general practitioner or pediatrician. The child's anamnesis and physical exam usually help set an accurate diagnosis, whereas paraclinical tests targeted to the most common group of diseases depending on the child's age will lead in most cases to setting the positive diagnosis. When determining the cause of abdominal pain and acute abdomen and subsequent therapeutic approach, communication is in most cases "the key to success"; both the questions asked and the explanations given to the family should be layman versions, spoken in a calm and reassuring voice and even repeated if necessary; direct communication with the patient, even when he/she is only a few years old, decreases the child's and family's stress and anxiety levels and strengthens their trust in the healthcare system. For instance, for children who are about to undergo surgery, there are there things which should be emphasized since they are essential: the fact that the child will not feel any pain during the procedure because he/she will be asleep, the fact that when he/she wakes up his/her parents will be there and the fact that he/she will then feel better and be able to go home (16). It is also important for the family to have time to think about and process the information received before giving their informed consent for the surgical procedures. This time will be used by the surgeon to analyze the biologist test results and imaging findings.

Time is of the essence for the doctor as well, since the clinical-paraclinical dynamic reassessment of a child with unclear clinical picture, or the child's reexamination 1-2 hours later, after his/her hydro-electrolytic and acid-basic rebalancing and after pain therapy administration, may reveal new signs. Biological tests and a few imaging procedures should be performed during this time interval, depending on the age of the child and initially suspected diagnosis. Monitoring the patient closely means that if intervention is required, this

can be done in a timely fashion, reducing post-operative complications.

CONCLUSIONS

Thorough anamnesis and full physical exam of the child suffering from acute abdomen who comes to the emergency room, followed by a set of tests and imaging investigations targeted depending on the patient's age and initial clinical suspicion, will in most cases distinguish medical from surgical etiology of acute abdomen of the child, and thus allow the timely initiation of an adequate therapy.

HEAD INJURIES IN CHILD (0-1 YEARS) (Abstract): Head injuries are one of the major causes of morbidity and mortality in children. The most common causes are falls from the same level. Boys are twice more prone to head injuries than girls. The traumatic pathology of the first 3 years of life is completely different when compared to that of adults. **Material and methods:** Retrospective study of all infants aged 0-1 years admitted for head injuries to the pediatric neurosurgery departments of "Bagdasar-Arseni" Hospital and "Sanador" Hospital in Bucharest. This 17-year study (January 1st, 2000-December 31st, 2016) included 509 patients aged 0 to 3 years. **Results**: Of these, 111 (21.8 %) were aged under 1 year, presented to the Emergency Department (ED), were hospitalized for at least 24- hour observation, and were diagnosed with at least one traumatic head injury visible on the imaging studies. The level of consciousness in infants was assessed by using a variant of the Glasgow Coma Scale (GCS) adapted to this age (0-1 years), namely Pediatric Glasgow Coma Scale (PGCS). CT with Bone-window is the first investigation in case of a head injury. **Conclusions:** Infants show a different pathology from that at other ages. Head injuries in infants pose multiple difficulties related to diagnosis, complications and follow-up. The data obtained from unenhanced CT scans constitute an emergency assessment. **Keywords:** HEAD INJURY, CHILD 0-1 YEARS, CT SCAN, PEDIATRIC NEUROSURGERY, GLASGOW COMA SCALE, GLASGOW PEDIATRIC COMA SCALE

Head injuries (HI) are one of the most important causes of mortality, morbidity and transient or permanent disability in the general population, both in adults and in children. In the USA, the incidence of HI among the children aged 0-4 years is about 1256/100,000 population (1, 2).

The clinical manifestations of pediatric and adult HI differ even when they share a common cause. Raimondi (1998) emphasized the importance of the differences between adult and pediatric pathology concluding that" the newborn is not a baby, the baby is not a school child", just "the teenager is not a child" and even more "adults are completely different from children" (3).

The most common causes of HI in infants are accidental falls from the same level or from height, traffic accidents in which children may be involved both as passengers and as pedestrians, accidents with various objects and child abuse (4).

When an infant presents to the Emergency Department with head injury, unenhanced CT brain scan is the initial imaging modality of choice. This is the "gold-standard" investigation for head injuries, and is preferred due to its accessibility and good visualization of bleeding injuries, solutions of continuity in calvaria with or without dural or cerebral expansion in the bone gap or cerebral edema lesions (5).

MATERIAL AND METHODS

All patients with HI aged 0 to 3 years admitted to the departments of pediatric neurosurgery of "Bagdasar-Arseni" Hospital and "Sanador" Hospital in Bucharest between January 1st, 2000 and December 31st, 2016 were included in this 17-year study. Of the 509 pediatric patients, 111 (21.8 %) were aged under 1 year. In this study group, we encountered a category of injuries caused by obstetrical trauma related to fetal dystocia or instrumental delivery.

All patients included in the study were admitted for at least 24-hour observation, and were diagnosed with at least one post-traumatic injury visible on imaging studies.

To analyze patients' state of consciousness, the authors used the Pediatric Glasgow Coma Scale (PGCS), a variant of the Glasgow Coma Scale (GCS) adapted for pediatric patients (6) (tab. I).

TABLE I

Pediatric Glasgow Coma Scale (6)

Best verbal response	Best eye response	Best motor response
No verbal response (1p)	No eye opening (1p)	No motor response (1p)
Inconsolable, Agitated (2p)	Eyes open to pain (2p)	Extension to pain (2p)
Inconsistently inconsolable, Moaning (3p)	Eyes open to speech (3p)	Abnormal flexion to pain (3p)
Cries but consolable, abnormal interactions (4p)	Eyes open spontaneously (4p)	Infant withdraws from pain (4p)
Smiles, orients to sounds, follows objects (5p)	N/A	Infant withdraws from touch (5p)
N/A	N/A	Infant moves spontaneously (6p)

RESULTS

The level of *consciousness* determined with PGCS in the 0-1-year group is presented in Table II.

As to the *etiology* of HI in infants the most common causes in this study group were falls from the same level or from another level and traffic accidents. A special category is represented by the injuries caused by physical aggression (tab. III).

TABLE II

PGCS evaluation of the level of consciousness in the 111 infants

GPCS	No. of cases	Percentage
15-13 points	79	71.1
12-9 points	20	17.9
<8 points	12	10.8
Total	111	100.00

TABLE III

Causes of head injuries in infants (0-1 years)

Cause	No. of cases	Percentage
Fall from the same level	41	36.9
Fall from another level	35	31.5
Road accidents	23	20.7
Accidents at play	5	4.5
Aggression (Child abuse)	4	3.
Other causes	3	2.7
Total	**111**	**100**

HIs are extremely varied, a frequent finding pallor, encountered in all study cases. Infants who were in pain were agitated and anxious. Another clinical category was the symptoms of increased intracranial pressure expressed by the anterior fontanelle bulging, vomiting, convulsive events, motor deficiencies or anisocoria and alteration of consciousness in various degrees (tab. IV).

TABLE IV

Clinical Symptomatology reported at Emergency Room

Clinical symptomatology	No. of cases	Percentage
Pallor skin	111	100
Irritability with agitation	60	54.1
Irritability and drowsiness	42	37.8
Anterior fontanelle bulging	39	35.1
Vomiting	26	23.4
Convulsive seizures	21	18.9
Motor deficits	15	13.5
Anisocoria	9	8.1
Impaired consciousness/coma state	12	10.8

The post-traumatic injuries seen on CT scans most frequently encountered in the hospitalized patients (111 cases; 21.8%) were: skull fractures of several types, cephalohematoma, extradural hematomas and DAIs (tab. V).

TABLE V

Head injury types on CT-scan examination in patients aged 0-1 year

Lesion type	No. of cases	Percentage
Cephalohematoma	15	13.5
Linear skull fracture	58	52.2
"Ping-pong" fracture	11	9.9
Progressive fracture	5	4.5
Intrusive fracture	6	5.4
Extradural hematoma	7	6.3
Subdural hematoma	1	0.9
Intraventricular hemorrhage	1	0.9
Diffuse axonal injury	7	6.3
Total	**111**	**100**

DISCUSSION

All head injuries in child 0-1 years should be very carefully assessed, and if craniocerebral injury is suspected native CT-scan is mandatory. The first CT-scan in the emergency department is very important for the following neurological, neurosurgical steps. Complementarily, brain MRI can also be used to detect traumatic injuries in the adjacent soft tissue and brain substance. Unfortunately, access to this type of examination is limited, examination time is longer, general anesthesia is required, and bone lesions are poorly visualized (7).

A distinct category of post-traumatic cerebro-ventricular injuries encountered in pediatric patients is represented by diffuse cerebral edema and diffuse axonal injury (DAI). These types of injuries significantly affect patient's consciousness.

As in adults, physical examination of pediatric HI cases should include the assessment of vital signs, level of consciousness, focal post-traumatic injuries, possible cervical spine injuries and damage to other systems and organs (polytrauma), if the case. Neurological examination is aimed at identifying the possible motor or sensory segmentation deficits, and signs and symptoms suggestive of cranial nerve dysfunction, etc.

The use of the Glasgow Coma Scale (GCS) is extremely difficult in the pediatric patients, particularly in preverbal children. For these reasons, over time, several coma scores have been developed specifically for children in attempt to compensate for their differences in verbal and motor capabilities, and the last and most useful is Pediatric Glasgow Coma Scale (GPCS) (Ong et al., 1996) (6). Other two pediatric coma scales used in practice are CHOP Infant Coma Scale (Durham et al., 2000) (8) and Starship Infant Neurological Assessment Tool (Birse, 2006) **(**9).

We will present clinical manifestations and treatment of traumatic lesions in infants:

Characteristic types of injuries encountered in patients younger than 1 year are the bleeding injuries-*cephalohematomas* (15 cases, 13.5%), caput succedaneum and subgaleal hematoma and fractures - progressive diastatic fracture and "ping-pong" fracture.

Cephalohematoma is a post-traumatic collection of blood located between the skull and periosteum. The most clinically important feature is that it is limited by suture lines. The causes are related to obstetrical traumas or difficult vaginal deliveries when there is incompatibility between maternal pelvic size and fetal head size. Usually, cephalohematomas are detected during the first days of life and are reabsorbed spontaneously in few weeks. Sometimes, they are also associated with underlying linear fractures. They occur predominantly at parietal level. Surgery is indicated in case of ossified cephalohematoma for esthetic reasons (7), and all cases were operated with favorable neurological and aesthetic results.

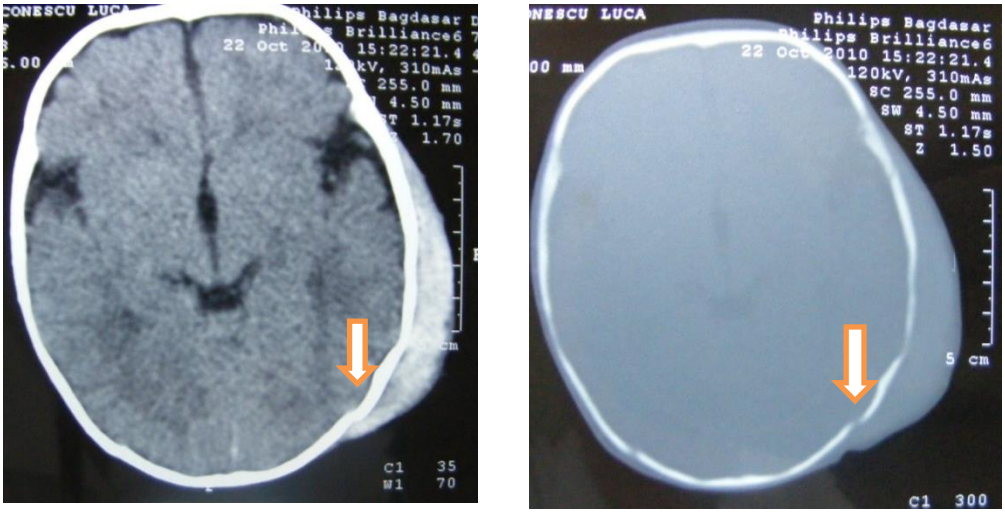
Among the types of fractures encountered there were *linear fractures* (58 cases, 52.2%) or *intrusive comminuted fractures* (6 cases, 5.4%) and particular types of fractures occurring only at this age, *diastatic fractures* due to the fact that suture fusion has not happened yet (5 cases) and *"the ping-pong" fracture* (11 cases, 9,9%), as the equivalent of" greenstick" fracture in the long bones. All the 11 cases were operated, immediately after diagnosis, with satisfactory results.

In these "ping-pong fractures", the individualized fracture paths cannot be detect-

ed, not even by imaging methods.

Solely skull deformation can be detected. In all "ping-pong" skull fractures it is recommended elevation of depressed calvaria soon as possible (10,11). In rare cases, this type of fracture may recover spontaneously (12).

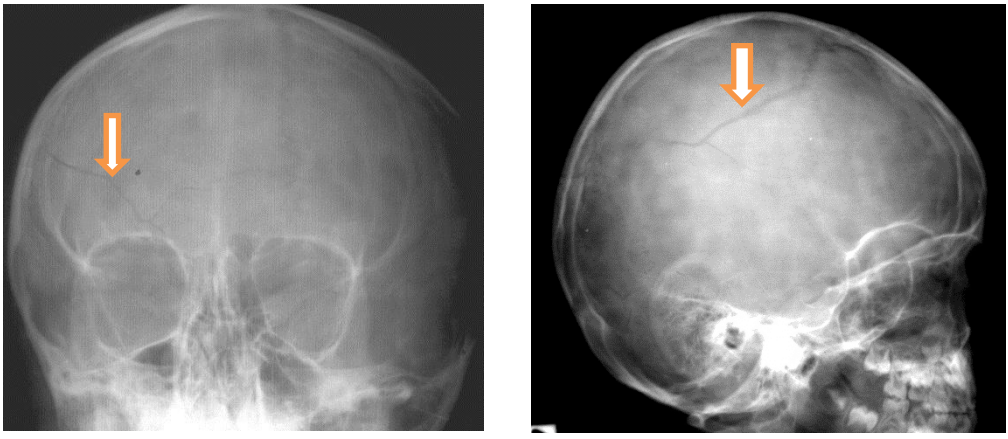
In case of *linear fractures*, hospitalization is required to monitor the patients. Linear fractures not associated with other injuries do not require surgical treatment, but they do require monitoring as an extradural hematoma may develop subsequently (fig. 1a and b).



a. CT- scan b. CT with bone window

Fig. 1. Liniar Fracture Left Parietal Bone

A different type of calvaria fracture is represented by the *diastatic fracture*, meaning the fracture involving the suture lines of the skull (5 cases) **(**fig. 2a and b).



a. Anteroposterior view b. Sagital Incidence

Fig. 2. Right fronto-parietal-diastatic fracture

One of the risks associated with a linear fracture, especially diastatic, is the potential transformation into a "*growing skull fracture*" **(**fig. 3).

Fig. 3. Left parietal progressive skull fracture

In this cases, meningeal structures and brain tissue could interfere between the edges of the fracture, preventing the consolidation process of the fracture. This process causes brain herniation between bone edges. Growing skull fracture needs neurosurgical extensive approach, removing gliotic tissue, CSF restoration, closing dura, cranio plasty. All the cases were operated with this procedure, before CT-scan evaluation, and MRI- scan. There were no death patients, but 3 from 5 cases remained with neurological deficits and seizure (13,14).

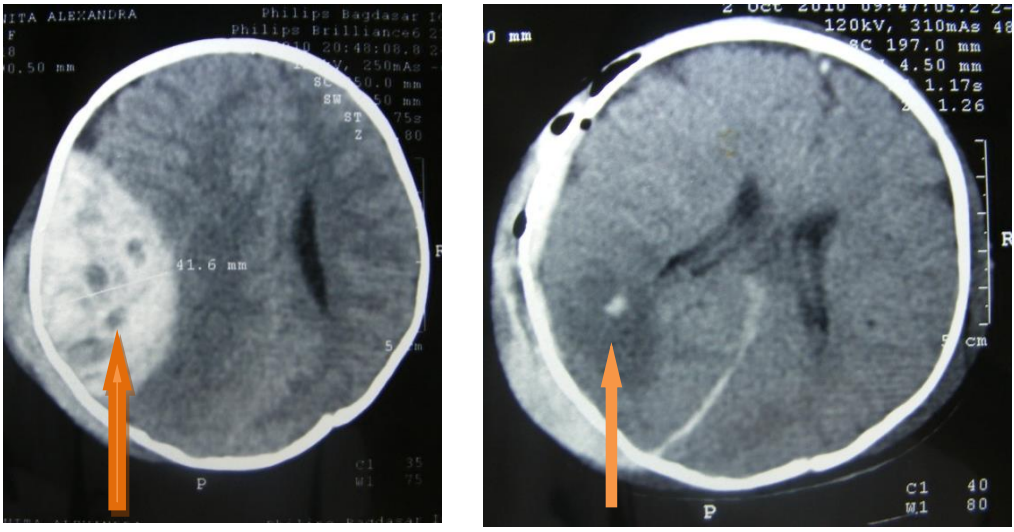
Comminuted skull fractures, with or without depressed bone fragments require surgery to reposition the fragments and to treat the underlying traumatic injuries, most likely related, because these fractures occur in case of high-energy trauma. Special attention is given to the management of comminuted fractures that are adjacent to or above the dural sinuses because of the major risk of important bleeding and hemorrhagic shock (15). All 6 cases (5.4%) were operated through a broad approach restoring cerebral structures, dural and skull, with favorable neurological outcomes; there was no postoperative death.

Post-traumatic head injuries that may be encountered are hemorrhagic brain contusion, diffuse brain injury and extradural, subdural, subarachnoid and intraventricular hematic collections. Any extra cerebrally hematic collection with compressive effect requires surgical evacuation and an adequate hemostasis to reduce intracranial hypertension that develops secondarily, with important consequences for the neurological status of patients. In our study, were 7 cases (6.03%) of *extradural hematoma* diagnosed and operated in time (7).

Results: 1 death patient, at the admission, CGS=3pts., with all the entire evacuation of the hematoma and intensive care measures could not be resuscitated, but rest of 6 cases (4 with good recovery and 2 with moderate disabilities (fig. 4).

Acute Subdural hematoma was present in one case (0.9%) but neurosurgical intervention was one time and postoperative evolution was favorable. Convulsive syndrome preoperatively, was treated with appropriate therapy.

In case of diffuse brain damage (DAI-diffuse axonal injury) (7 cases- 6,3%), which is usually associated with a poor neurological status and impaired consciousness, the aim of the initial treatment is to preserve the vital functions and minimize intracranial hypertension through nonsurgical methods. Unfortunately, these types of diffuse injuries have an extremely poor prognosis (with 2 died), despite all therapeutic measures taken (7).



a. preoperative appearance b. postoperative appearance

Fig. 4. CT-scan: Extradural hematoma in a 4-month-old infant

The Glasgow Outcome Scale (GOS) at 6 months was used for the assessment of functional outcome and prognosis, a favorable score (GOS = 5) being obtained in 65 (57.8%) of the cases (tab. VI).

The other 3 patients (2.8%) died because of extremely serious diseases: (2 death cases involving Diffuse axonal injury) and 1 case extradural hematoma

The authors draw attention on the unpredictability of clinical course in these patients, thus requiring a more complex and unitary therapeutic approach to maximize the probability of a favorable course due to the great functional resources of this patient population (**7**). Also, they emphasize that head injuries in infants is an important public health problem (4, 9).

TABLE VI

Outcome in Head Injuries - 111 of cases studied at 6 months

Glasgow Outcome Scale (GOS)			Number of cases	Percentage
5	GR	Good-recovery	65	57.8
4	MD	Moderate disability	25	22.3
3	SD	Severe Disability	13	12.3
2	VS	Vegetative state	5	4.8
1	D	Death	3	2.8
Total			**111**	**100**

CONCLUSIONS

From the point of view of therapeutic solutions, difficulties arise regarding the patients' youthful age, with multiple difficulties regarding diagnosis and monitoring of injuries, as patients have limited ways of expressing themselves. On the other hand, it is also necessary to adopt procedures that

limit blood loss, given the low capital of these patients, without neglecting the risks of significant neurologic deficits.

Concerning the laboratory investigations, brain CT scan is the gold standard in case of emergency examinations, with a high degree of identification of lesions in a reduced examination time.

Therefore, prevention of these head injuries by effectively supervising children and sending them in due time to a neurosurgical service, in case of signs and alarm symptoms, plays a very important role in achieving the most favorable results in terms of vital and functional prognosis of this category of patients.

SUCCESSFUL AGING IS INFLUENCED BY FRAILTY AND HEALTH-RELATED QUALITY OF LIFE IN COMMUNITY-DWELLING SENIORS (Abstract): Successful aging at maintaining and enhancing elders' health and functioning for if possible. Frailty, a new concept in medicine, was found to be the main cause of disability and death, therefore it has an important influence on quality of life in these patients. **Aim**: To identify the prevalence of frailty in home-dwelling elderly and its influence on quality of life. **Material and methods**: The study was conducted on a group of non-hospitalized elderly (>65 years) without no prior hospitalization in the past 3 months who volunteered to take part in a geriatric assessment occasioned by the Day of Older Persons on October 1, 2016. Frailty was assessed using Fried phenotype, Groningen Frailty Indicator (GFI) and comprehensive geriatric assessment. SF-36 was used to assess the quality of life, and the participants were also asked to provide information on their medical history and medical treatments. **Results**: The study showed a low prevalence of frailty in non-hospitalized elderly people (27.77%), with higher scores recorded on GFI, but given the small sample size the correlations were not statistically significant. Quality of life was significantly decreased in the frail subjects both in terms of physical and mental function, with lower scores on the physical component. **Conclusions:** These findings suggest that early detection and intervention are essential for improving quality of life of frail elderly, one of the main elements of successful aging. **Keywords:** SUCCESFUL AGING, FRAILTY, QUALITY OF LIFE, ELDERLY

Increasing life expectancy is a well-known global phenomenon, which has led to the increase in the elderly quota, that is of people over 65 years of age; unfortunately, this phenomenon is not accompanied by a proportional increase in the youth quota, in order to keep harmonious proportions between the active and the retired population, and therefore, over the last thirty years, we have been witnessing a new demographic phenomenon known as population aging. This situation has numerous consequences, on many different levels: economic, social, medical, spiritual, implicitly requiring the generation of new projects and policies to address the health of the elderly.

Successful aging is one of these projects, which aims at preserving, for as long as possible, an acceptable level of health for the elderly (1). To achieve this goal, each older person should be assessed by a

geriatric multidisciplinary team that would develop an individual plan of measures to ensure a smooth transition and, if possible, without the interference of diseases, through the various stages of the physiological aging process. These individually tailored therapy plans have as end-goal the preservation of the quality of life and the physical, mental, spiritual, financial and social independence for if possible, trying to shorten to the maximum the final period burdened by suffering, sickness, disability and dependence (2, 3).

The prevalence and definitions of successful aging vary among studies (4); however, there is a consensus regarding its multidimensional nature, and one of the most important components is quality of life.

Quality of life (QOL) has an individual, multifactorial and dynamic nature. It is constantly related to past experiences and influenced by future expectations, which means that for an older person the quality of life changes its significance while aging (5). The Short Form-36 (SF-36) is a multidimensional scale and a well-established instrument that measures health concepts and self-reported quality of life (6).

Successful aging must also consider the degree of frailty of the elderly, an inherent phenomenon of progressive deterioration in the function of all body organs and systems, thus increasing the degree of vulnerability to various stress factors. Thus, frailty becomes a key element in ensuring successful aging. Initial studies focused on physical frailty because this was the most visible aspect in the physiological decline process, also having severe consequences on physical independence, increase in sedentary time and metabolic and cardiovascular diseases, increasing the degree of disability and the need for high-cost medical care (7). Subsequently, attention was drawn more to the phenomenon of mental and social frailty, which, in their turn can induce physical frailty (8). Evaluation of all elements of frailty is preferred in all recent studies.

Systematically applying the frailty scores to the elderly population would lead to the identification and classification of frailty in terms of stages; early intervention to combat this syndrome can make the difference between autonomy and dependence, between active and bedridden and, finally, between an optimal quality of life and the "burden of old age". The authors of recent studies still consider the best assessment and classification of frailty as being the result of a comprehensive geriatric assessment (9, 11, 12).

The impact of frailty syndrome on the quality of life of the elderly has become a subject of interest. Recent studies focus on determining the degree of negative impact of frailty syndrome on the quality of life of the elderly, but also on determining the manifestation with the highest impact on the decrease in QOL (10, 11, 12).

MATERIAL AND METHODS

The study was conducted on a group of 36 elderly persons (aged over 65) registered with family doctors and who volunteered for a geriatric assessment occasioned by the Day of Older Persons on October 1, 2016. All participants signed an informed consent and were free to withdraw from the observational study at any time. This group included all elderly persons with no acute diseases at the time of the presentation and/or who were not hospitalized for acute events over the past 3 months.

The geriatric assessment tried to capture various aspects of each participant in order to achieve an appreciation that is as close as possible to reality and which to generate an individualized therapeutic plan. In this regard, the participants filled in the following questionnaires: SF-36 (for assessing the

QOL), EASY (for the assessment of frailty through the Groeningen test) (fig.1), MMSE scale (assessment of cognitive status), MNA (assessment of nutritional status), GDS depression scale (assessment of emotional status), ADL and IADL scales (assessment of the ability to participate in daily activities). Besides these questionnaires, the participants were asked to provide information on their past medical history and the medication they take at home (including OTC); also, the parameters that define sarcopenia were assessed and anthropometric measurements were performed to calculate the Fried fragility score (tab. I).

TABLE I

Fried phenotype

Weakness	Grip strength <20% in the dominant hand
Slowness	<20% for time to walk 4.5 m
Low level of physical activity	<20% for calories expenditure
Exhaustion, poor endurance	Self- reported
Weight loss	Unintentional loss 4-5kg in 1 year

Fig.1. Groeningen test (25)

Using SF-36 to define successful aging is an acceptable tool because it assesses the overall health status in two directions: the physical component summary and the mental component summary, which are generally used to define health status.

The calculation of the Fried frailty score led to the division of the group into 3 subgroups:

- Subgroup 1- robust elderly persons (20 people) - no Fried criteria;
- Subgroup 2 - pre-frail elderly persons (6 people) - 1-2 Fried criteria;
- Subgroup 3 - frail elderly persons (10 people) - 3 or more Fried criteria.

The data were loaded and processed with the help of statistical functions in *SPSS 18.0*: ANOVA test - descriptive indicators of the monitored parameters (minimum, maximum, average, standard deviation, standard error, variance, confidence interval 95%), FANOVA - quantitative test used to study the significant difference between mean values in two or more groups, the χ^2 test - qualitative test that compares two or more frequency distributions in the same population.

RESULTS

The analysis of the demographic data indicated that patient age ranged from 65 to 89 years, mean age 75.5 years; most subjects (72.22%) were women, both in the initial group and in the 3 subgroups: 66.66 % in subgroup 1, 100% in subgroup 2 and 60% in the subgroup with frailty. These results support the data in the literature showing a significantly increased prevalence of frailty among female population (13,14). But, other studies report no significant gender differences in the prevalence of fragility, but emphasize a higher risk of mortality in men with clinically manifest frailty (15).

The conducted study showed a low prevalence of frailty among the non-hospitalized elderly people (27.77%), but the small size of the study group does not allow us to determine statistically significant data.

High Groningen scores were recorded both in the subgroup of robust elderly people (50%) and in the subgroup of frail elderly people (80%). No statistically significant correlation was found between the two used screening methods ($p = 0.285$). By using two screening tools for frailty, different degrees of impairment in the study group were identified. Thus, we found a slight overvaluation of frailty by using the Groeningen test. This tool is based on self-evaluation from the patient and is thus influenced by his/her perceived health status. The Fried score, though more succinct, includes quantifiable objective elements (muscle strength, walking speed decrease). Also, the ability to identify pre-frail subjects by using the Fried score extends its clinical utility, the measures for inducing the reversibility of frailty are believed to have the best result in the stage of pre-frailty.

The analysis of the questionnaire responses showed that the elderly enrolled in the study had no cognitive deficit and have a high degree of independence in carrying out daily activities. The GDS depression score was not significantly correlated with frailty ($p=0.184$), but there was noted the prevalence of the depressed people in the subgroup of frail subjects (40%), which confirms the role of the emotional status in the emergence and aggravation of frailty syndrome, element often omitted by the screening tools currently available, but easily identifiable by a comprehensive

geriatric assessment. The depressive syndrome in the elderly has a negative impact on QOL, nutrition, hygiene and therapeutic compliance, but once identified it benefits from specialized treatment and counselling (16).

The analysis of the SF-36 questionnaires showed that the QOL score for the physical component ranged from 25.2 to 93 with a mean score of 65,022. No significant correlation with the Fried score was found, but a higher QOL level was found in the subgroup without frailty, and a significant decrease in those with frailty (fig. 1, 2). The score for the mental component ranged from 20.70 to 98.00, with a mean score of 69.58. There was no significant correlation with frailty, but there can be noted a low level QOL in the subgroups of pre-frail and frail subjects (fig. 3, 4).

DISCUSSION

Frailty syndrome was initially considered the prerogative of older people, being associated with and sometimes overlapping disability, the presence of concomitant chronic diseases and a high degree of de-

pendence. However, the results of our study show no correlation between age and the increase in the degree of frailty, thus making a clear distinction between physiological aging and frailty syndrome, supporting the data in the literature (17,18).

Most authors (9, 10, 11) consider that there are three stages of frailty. The first stage, preclinical, corresponds to a state in which the body has sufficient physiological reserves to respond to external or internal aggression factors, such as the aggravation of a disease, trauma or stress. Preclinical frailty is completely reversible, being the stage during which full recovery is possible, especially if the elements requiring intervention are identified.

The second stage is that of clinically manifest frailty, corresponding to a state in which the available functional reserves are insufficient. During this stage, recovery is incomplete, but a well-thought-out therapeutic plan, adapted to the patient's profile can favor the transition towards the pre-frail stage, with an obvious improvement of health and quality of life.

The final stage of frailty is that of frailty-related complications and is related to severe physiological vulnerability and reduction of functional reserves. The body is no longer able to cope with aggressions, leading to an increased risk of falls, disability, polypharmacy, prolonged hospitalizations, severe infections, institutionalization and death.

The initial findings of Fried et al. (19), supporting an increase in the prevalence of frailty syndrome once every five years, were confirmed by subsequent studies, one of the most important being conducted by Gill et al. (20), as part of a longitudinal study which observed and confirmed the transition between the three stages of frailty during the 4.5 years of follow-up. This transition is directly dependent on patient's initial frailty state, supporting once again the opportunity for screening and early diagnosis of frailty (21). Progression towards a more severe stage of frailty is more common than transition towards a lower stage, one of the causes being also the defensive medicine practice, addressing the frailty-related complications: treatment of falls, cognitive decline or immobilization. The association of sensory and cognitive deficits along with polypharmacy and the tendency towards therapeutic and diet non-compliance participate in the aggravation of chronic diseases, with repeated decompensations, frequent hospitalizations and the progression of frailty (22).

The assessment of the degree of frailty remains an intensely discussed topic, numerous studies conducted over the past 20 years suggesting various scales and tests. Using different measurement tools led to different results, hard to compare in identifying frailty, which led to the conclusion that the use of at least two tools for measuring frailty are necessary (22). Our study used the Groningen and the Fried scale; the results show that the Groningen test could not determine the pre-frail stage in the study group, along with an over-diagnosis of frailty in the group of robust older persons. By analyzing these data, we conclude that the comprehensive geriatric assessment remains the golden standard method for the diagnosis of frailty, provided that it is conducted by a team with experience in drafting the questionnaires and interacting with elderly persons. These findings are consistent with the numerous studies carried out throughout the world in recent years (23, 24). These results underline the need to adopt a tool for diagnosing the stages of frailty that is easy

to apply within primary health care or to facilitate the access of the elderly to geriatric centers with experience in the field.

Quality of life was poorer in the subgroup of frail compared with robust persons. The physical component has recorded lower scores than the mental component, which leads to the need of determining the other influencing factors, as well as the impact of frailty on each element related to quality of life. The multiple special aspects of QOL in the elderly require a more specific assessment, including the features of the individual in terms of expectations, social or family environment.

Disabilities, dependence and repeated hospitalizations experienced by elderly people due to frailty, adversely have a negative impact on quality of life. In this age segment, physical health has a more important role in the quality of life, thus the implementation of measures aimed at reversing the frailty syndrome can maintain the state of wellbeing and ensure successful aging.

CONCLUSIONS

We presented the preliminary results of a prospective study that shows that frailty has a significant influence on the quality of life of the elderly, but medical, psychological and social particularities in this age group require a specific QOL assessment tool.

The comprehensive geriatric assessment remains the most appropriate method for an accurate diagnosis of frailty, but it requires time and the expertise of a geriatrician, thus making it difficult to use as a screening method in the primary medical practice.

NEWS

USE OF PCR TECHNIQUE FOR IDENTIFICATION OF *MICROSPORUM* SPECIES

The identification of species in the *Arthroderma otae* complex is necessary in order to determine the source of infection and reduce the risk of transmission. *Microsporum canis* is a zoophilic species, whereas *M. audouinii* and *M. ferrugineum* are anthropophilic. In a paper published by Kobylak *et al* an alternative method is proposed to allow species-specific identification of both anthropophilic and zoophilic species. For this purpose, two PCR assays (both traditional and real-time) were designed based on differences in the DNA fragment encoding β-tubulin and were applied using DNA extracted from pure culture. The two assays were able to identify *M. canis* and *M. audouinii/M. ferrugineum* with 100% sensitivity and specificity. These methods can be applied in routine laboratory praxis and are also useful for epidemiological studies (Kobylak N, Bykowska B, Kurzyk E, Nowicki R, Brillowska-Dąbrowska A.PCR and real-time PCR approaches to the identification of *Arthroderma otae* species *Microsporum canis* and *Microsporum audouinii/Microsporum ferrugineum*. *J Eur Acad Dermatol Venereol.* 2016 Jun 15. doi: 10.1111/jdv.13681. CONTROVERSIES ON TRANSVAGINAL ULTRASOUND SCREENING FOR ENDOMETRIAL CANCER IN ASYMPTOMATIC POSTMENOPAUSAL WOMEN (Abstract): Endometrial cancer (EC) in postmenopausal women is usually associated with abnormal vaginal bleeding. However, asymptomatic cases of EC have been reported. The incidence of EC has been estimated to 1.3-3.05 per 1,000 screened postmenopausal asymptomatic women, the most significant ultra-sonographic feature being the thickened endometrium. We reviewed the literature on the accuracy of endometrial thickness measurement by transvaginal sonography (TVS) in predicting EC in asymptomatic postmenopausal women. The use of endometrial thickness as a sole screening test was found not to be of high predictive value and it should be combined with the evaluation of EC risk factors and followed by hysteroscopy and biopsy in suspicious cases. The lack of a universal cut-off value for endometrial thickness that could be correlated to EC is pointed out. **Keywords:** ENDOMETRIAL CANCER, ENDOMETRIAL THICKNESS, TRANSVAGINAL ULTRASOUND.

Endometrial carcinoma (EC) is the most common malignancy of the female genital tract in developed countries with over 60,000 new cases and over 10,000 deaths from the disease in each year (1). Endometrial cancer affects mainly postmenopausal women. The mean age of women diagnosed with endometrial cancer is 60. It is uncommon in women under the age of 45 (2). Adenocarcinoma of the endometrium is the most common histologic type of uterine cancer.

Postmenopausal vaginal bleeding is the presenting sign in more than 90% of postmenopausal women with EC and is associated with an up to 10% risk of EC (3), the most common cause of postmenopausal bleeding being endometrial atrophy (4).

Risk factors for EC are nulliparity, early menarche age, obesity, diabetes, hypermenorrhea, tamoxifen therapy and hirsutism-polycystic ovary syndrome. Measurement of endometrial thickness by transvaginal sonography (TVS) is a valuable test for estimating the risk of EC in women with postmenopausal vaginal bleeding (5). TVS is a non-invasive and painless procedure, has no complications, requires no special preparation, may be more sensitive in detecting carcinoma than blind biopsy, has a high cancer detection rate, is widely available and the cost is like biopsy (6, 7). Color and spectral Doppler ultrasound examination of uterine and the sub endometrial arteries can aid in the differential diagnosis of benign and malignant endometrium (8, 9). Seven to seventeen percent of postmenopausal women diagnosed with EC have no symptoms at the time of diagnosis**.** The incidence of asymptomatic EC has been reported to range from 1.3 to 1.7 per 1000 screened postmenopausal women (10, 11). The value of endometrial thickness measurement in healthy, asymptomatic postmenopausal women has not been documented yet. The general need for EC screening in these women is questionable and there is lack of consensus regarding the clinical significance of endometrial thickness measured by TVS (12-14).

The aim of this review is to determine the utility of endometrial thickness cut-off value for endometrial sampling in asymptomatic postmenopausal women who do not use Hormone Replacement Therapy (HRT).

TRANSVAGINAL SONOGRAPHIC EVALUATION OF THE ENDOMETRIUM IN ASYMPTOMATIC POSTMENOPAUSAL WOMEN

Endometrial thickness is measured as double-layer thickness at its thickest part in the longitudinal plane; homogeneity and echogenicity should also be mentioned. Values of 2-3 mm are considered normal atrophy, whereas a thickened endometrium may represent malignancy, hyperplasia or polyps. Also, to be considered 'normal', the endometrial lining must be regular and clearly visible over the totality of the uterine cavity (15). In symptomatic postmenopausal women, a cut-off value for endometrial thickness of 4-5 mm has been established. Although advanced EC has been identified in cases without noticeable endometrial thickness on TVS, the probability of endometrial cancer below this value is 1% (16, 17).

Little is known about endometrial thickness in healthy asymptomatic postmenopausal women. Universal **s**creening for endometrial malignancy is not considered necessary. The mean endometrial thickness in postmenopausal women without vaginal bleeding ranges between 3-5 mm (18-20). The risk of EC in women with endometrial thickness less than 5mm is approximately 1% compared to nearly 20% if the measurement is above this threshold (21, 22). A recent meta-analysis suggested that endometrial thickness > 11mm carries a risk of 6.7% for EC in asymptomatic postmenopausal women (23). The risk of malignancy was found to be small (1%) when a low cut-off value of 4mm was used (24). In a retrospective study among asymptomatic postmenopausal women with endometrial thickness ≥ 5mm, 0.9% was diagnosed with EC after endometrial sampling and 12.2% were diagnosed with atypical hyperplasia. For a cut-off value of 5mm, 106 endometrial samplings needed to be performed for the diagnosis of one case of EC (25). For the detection of all intrauterine pathologies the best cut-off value was found to be >8mm with a positive predictive value of 10.05. The sensitivity for EC was 100% at a cut-off value >10

mm (26). In patients referred to hysteroscopy due to thickened endometrial lining, TVS had a total false positive rate of 93.2% and a positive predictive value of 0.7% for EC (27). Retrospective studies of postmenopausal asymptomatic women with TVS endometrium thickness > 5 mm who underwent diagnostic hysteroscopy and biopsy found less than 1% atypical hyperplasia, with most findings (>80%) being atrophy, simple hyperplasia and polyps (28, 29). Endometrial cancer can be diagnosed early by TVS in a prognostic ally better stage in asymptomatic patients.

Another meta-analysis concluded that the use of TVS endometrial thickness as a screening method in asymptomatic postmenopausal women not on HRT is not justified because of the low incidence of endometrial cancer in the observed population and the insufficient data from the published studies to calculate an optimal threshold for endometrial thickness based on the sensitivity and specificity (30, 31).

The cut-off values for endometrial thickness in asymptomatic postmenopausal women determined by various research groups are presented in Table I (32-35).

TABLE I

Endometrial thickness and cancer findings in postmenopausal asymptomatic women

Author	Endometrial thickness (mm)	Number of women	Number of cancer cases	Negative of predictive value%
Osmers et al. 1990	≥ 4	283	10	96.50
Osmers et al. (1994)	≥ 8	88	18	79.55
Abu Hmeiden et al. 1992	≥ 10	24	3	87.50

Bakos et al. 1995	>6	106	1	99.00

Controversies also exist regarding the significance of intrauterine fluid collection in postmenopausal women. It can be considered as an ominous sign associated with malignancy even in the presence of thin endometrium, or it may represent fluid transuded from an atrophic endometrium which accumulates in the uterine cavity due to cervical stenosis**.** Small series of such patients reported endometrial mommas,

polyps, hyperplasia and rarely endometrial carcinoma, especially if endometrial thickness was greater than 4 mm (36).

DISCUSSION

TVS is being used in the last years as an accurate tool to identify endometrial pathology, including endometrial carcinoma in both symptomatic and asymptomatic postmenopausal women. In asymptomatic women diagnosed incidentally with a thick endometrium, a clinical dilemma concerning the case management arises. While the main presenting symptom is abnormal uterine bleeding, 7% to 17% of endometrial cancers are found in asymptomatic postmenopausal women. Despite the established association between a thick endometrium and endometrial carcinoma in postmenopausal women with vaginal bleeding, there is a lack of consensus regarding the asymptomatic postmenopausal women. Most of the researchers agree that in postmenopausal asymptomatic women endometrium thickness < 3 mm strongly reduces the probability of endometrial pathology, while endometrium thickness > 10 mm is correlated with pathologic histology. But there is a 'gray area' between 4 and 10 mm that needs further investigation, as sometimes EC is found. Most cases of EC in postmenopausal asymptomatic women have endometrial thickness measured with TVS over 5 mm.

The recommendations of the Society of Obstetricians and Gynecologists of Canada (37) state that TVS should not be used as a screening method for endometrial cancer in asymptomatic postmenopausal women not using HRT. In women with incidentally observed thickened endometrium and other positive ultrasound findings (increased vascularity, inhomogeneous endometrium, intrauterine fluid, thickening>11mm) together with endometrial cancer risk factors, case-by-case decisions and further investigation such as endometrial sampling is recommended.

In conclusion, transvaginal sonography (TVS) is a reliable, non-invasive method for the evaluation of the endometrial thickness and morphology in asymptomatic postmenopausal women. Universal endometrial screening is controversial because of the lack of evidence of increased 5-year survival rate for EC patients. The diagnostic success of this method also depends on examiner's training and experience. The difficult issue of how to manage an asymptomatic postmenopausal woman with an incidentally discovered thick endometrium has yet to be resolved. We believe that TVS should be combined with clinical signs and risk factors for endometrial cancer to achieve the optimal management and avoid unnecessary invasive interventions, procedural complications and psychological stress.

IMPLICATIONS OF HYSTERECTOMY ON VAGINAL ROUTE IN GYNECOLOGIC PATHOLOGY

IMPLICATIONS OF HYSTEROCTOMY ON VAGINAL ROUTE IN GYNECOLOGIC PATHOLOGY (Abstract): Vaginal hysterectomy was mentioned before our era by Soranus of Ephesus, and it is one of the most frequent surgical interventions in gynecologic practice; performed for the first time by Sauter of Constance, in 1822, who practiced a vaginal hysterectomy without ligation of vessels, carrying out the hemostasis with a swab dipped in alum. The essential argument for vaginal surgery is the advantages it brings. Current indications and contraindications encourage the frequent use of vaginal hysterectomy in benign pathology of the uterus, while the indication (Crossen, Rouhier, Campbell techniques) depends most of the times on the surgeon's experience and preference rather than on the critic evaluation of results. **Material and methods:** The study group included 84 patients, hospitalized from January 2013 to December 2015 in the Third Obstetrics Clinic. For the evaluation of results, we used longitudinal retrospective clinical-statistical method. **Results and discussion:** Practicing the surgery on vaginal route is mainly indicated in patients with severe anemias and different organic tares. When removal of the cervix is not indicated, or when there is an enlarged uterus or one with a small diameter, it is recommended to use laparoscopic hysterectomy. **Conclusions**: Vaginal hysterectomy is a technique that allows rapid removal of the uterus, with a minimal impact on the patient, indicated in the pathology of benign uterine tumors (uterine fibromatosis associated with metrorrhagia, fibromatous uterus with cervical dysplasia, or fibromatous uterus associated with different degrees of uterine prolapse).
Keywords: VAGINAL HYSTEROCTOMY, BENIGN TUMORAL CONDITIONS, HEMORRHAGE.

When the size of the uterus is not very big, hypogastrium does not have many adherences, there are no pathological changes and if the diameter of the vagina allows, hysterectomy on vaginal route is possible, either under epidural anesthesia – with a total limitation of mobility and senses –, or under general anesthesia (1).

For patients, it is more comfortable, while the operatory time, hospitalization days and recovery time are shorter than in cases of abdominal interventions.

Vaginal hysterectomy is an accepted method in patients with uterine descensus, whose basins allow vaginal surgery, whose tumors are small enough to allow the vaginal technique, and if the patients consent to be operated via vaginal route (1,2).

When there are large fibromas, pretreatment with a GnRH analogue will allow

the vaginal surgery, which was previously impossible (3,4).

Removing the uterus and cervix, also the stability of the vagina is reduced, as well as the future onset of a vaginal prolapse by applying special sutures; rarely there can be inflammations and/or bleedings, which can be shortly resolved by medical treatment or short local vaginal treatments (6,7).

In November 2009, ACOG (The American Congress of Obstetricians and Gynecologists), through the Committee on Gynecologic Practice, published an opinion that recommended vaginal hysterectomy as the safest and the most cost-effective method of uterus removal for non-neoplastic indications. Without changing the eligibility criteria for vaginal hysterectomy issued in 1989, the authors pointed out the fact that the surgeons can decide, depending on their technical skills, to use VH (vaginal hysterectomy) even when there are apparent contraindications (8).

The paper aims at highlighting particularities on the place and value of hysterectomy on vaginal route in resolving the most frequent surgical gynecologic conditions (uterine fibroma, conditions of genital apparatus associated with chronic diseases, septic states, advanced age, and organic tares).

MATERIAL AND METHODS

The study group of the retrospective longitudinal study included 84 patients, hospitalized from January 2013 to December 2015 in ”Elena Doamna” Clinical Hospital of Obstetrics and Gynecology of Iasi, under the service of Third Clinic of Obstetrics-Gynecology.

The inclusion criterion was preoperative indication of hysterectomy for benign pathology.

The information was collected from the patients’ observation charts, surgical interventions register and histopathological records. We monitored the features of the field – age, environment of origin, number of cases of vaginal hysterectomy for the associated uterine pathology (benign tumors) and the diseases of the adnexa’s, as well as the advantages and disadvantages of the method.

RESULTS AND DISCUSSION

Although hysterectomy is a surgical routine, its costs and morbidity in relation to this intervention had a significant economic impact on the health and social systems (8).

Within the period of time included in the study, 84 cases of vaginal hysterectomy were performed (tab. I), with various distributions on age groups (tab. II).

TABLE I

Yearly distribution of the cases of vaginal hysterectomy

Year	Vaginal hysterectomy	
	No.	%
2013	21	25.00
2014	34	40.47
2015	29	34.53
Total	84	100.00

TABLE II

Structure on age groups

Group (years)	No.	%
Under 30	3	3.57
31 - 35	14	16.66
36 - 40	9	10.73
41 - 45	22	26.19
46 - 50	10	11.90
51 - 55	9	10.72
56 - 60	13	15.47
→61	4	4.76

The frequency of obstetrical antecedents showed insignificant differences in relation with the number of pregnancies (tab. III).

TABLE III
Obstetrical antecedents of the study group

Frequency of births in antecedents	No.	%
1	**25**	29.76
2	31	36.90
3	28	39.34

Similar to other authors (9,10), we evaluated in our study the possible risks related to the nature of obstetrical and gynecologic antecedents, presence of comorbidities, drug allergies and ongoing therapies.

Vaginal hysterectomy in benign tumor pathology needs lab investigations: CBC (Complete Blood Count), blood type, glycaemia, urea, creatinine, coagulogram, urinalysis, urine culture, as well as cytological and bacteriologic examination of vaginal discharge. In some cases, it is possible to practice electrocardiogram, pulmonary radioscopy, echography with vaginal ultrasound probe, or intravenous urography. To eliminate neoplastic pathology, we performed biopsy curettage a month prior to surgical intervention, and to prevent post operatory infection, we administered second generation cephalosporin intra operatory, or 500 mg metronidazole, intravenous.

When cervix removal is not indicated, or there is an enlarged uterus, or a small diameter of vagina, laparoscopic hysterectomy is recommended. Thus, on one hand, the pathogenic agents in vagina don't reach the abdominal organs, and on the other hand, the stability of hypogastrium is maintained. When choosing the vaginal route, we considered the anatomical condition of each case, mobility of the uterus and the vaginal caliber (11,12).

A special situation arises when the polyfibromatous uterus is associated with different degrees of genital prolapse and stress urinary incontinence (tab. IV, fig.1).

TABLE IV
Some indications of vaginal hysterectomy

Main indications	Cases	
	No.	%
Uterine fibromatosis associated with different degrees of uterine prolapse	19	22.61
Uterine fibromatosis associated with metrorrhage	27	32.14

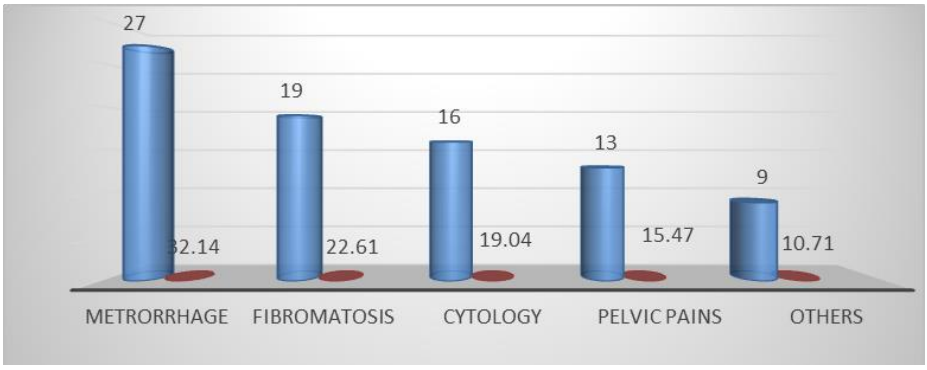

Fig.1. Indications for vaginal hysterectomy

We obtained special results in cases with prolapse; hysterectomy was supplemented by a suspension of the bladder and vaginal stump through the straps of the adnexa and ligaments, plus anterior colporraphy and posterior colpoperineorraphy.

Although other authors, too (10,11) admit that the main complications after vaginal hysterectomy can be stump hematoma, local infection, bladder and intestinal wounds, the most important complications are intra- or post operatory bleedings, infection, lesions of neighboring organs, thromboembolic complications etc.

The surgeon may decide, according to its technical possibilities of the use VH even in the presence of an apparent contraindication.

During the vaginal hysterectomy, predictable bleedings occurred in 3(3.57%) cases (bleeding from the vaginal trance, difficulties of detachment from myometrium from myometrium); 2 (2.38%) cases with accidental losses of blood due to incorrect ligatures, their secondary sliding and accidental rupture of vascular pedicles; 11(1.14%) patients presented delayed post operatory bleeding, in the third week, caused by the active bleeding from the vaginal stump. The complications we faced consisted of one case with vaginal stump abscess and two cases with bladder lesions due to close adherences; 6% needed surgical intervention.

TABLE V

Post operatory complications occurring in the study group

	Cases	
Complication	**No**	**%**
Bleeding	6	7.14
Bladder lesions	2	2.30

We evaluated the results post operatory one month, two months, four months and one year after the surgery.

Vaginal hysterectomy makes that the main changes arising post operatory are determined by the absence of the uterus from the pelvis, with redistribution of abdominal pressure on the pelvic floor. As any other type of hysterectomy, it can cause emotional changes which can be easily prevented by means of post operatory discussions and adequate treatment, including hormonal therapy (tab. V).

DISCUSSION

Vaginal route allows wide access of intrapelvic genital organs, wide array of gynecologic surgeries of the uterus and adnexa, from the simplest ones, such as myomectomy, salpingectomy, tubal ligation, to total hysterectomy and enlarged hysterectomy for cervical cancer.

According to ACOG, the upper limit of the size of the uterus is indicated to be extracted via the vaginal route is corresponding to a load of 12 weeks, which corresponds to a weight of about 280 g.

While some authors such as Donald-Fothergill, Manchester (quote,11,13), are still using vaginal surgery procedures which involve saving the uterus, most of the authors prefer radical surgeries, removing the uterus in order to avoid post operatory relapses, or the risk of the onset of benign or malignant tumors on the remaining uterus (3,7).

Kovac (13), one of the best specialists in vaginal surgery, has dedicated a great part of his career in redefining the indications of vaginal hysterectomy from modern perspectives; he knocks down, step by step, based on scientific evidence of wide personal series, most of traditional contraindications.

Lamman and Krige (quote 13) take uterus removal on vaginal route as a major indication. In 1984, Guillemin and Cavalhier (5, 12) proposed vaginal hysterectomy as an optimal treatment method.

Vaginal surgery can be performed with multiple anesthesia methods, the choice of the type of anesthesia depending on the anesthesiologist's preference and the anesthetic risk. Post operatory infection in total hysterectomy has a low incidence as a result of intra operatory prevention with antibiotics (2)

Worldwide, there is an increase demand for total hysterectomy with adnexectomy, a demand that is more and more frequent in Romania as well (15).

CREST study was performed, in which indications for abdominal hysterectomy were distributed as follows: uterine fibroma (40%), chronic pelvic pain and endometriosis (22%); for vaginal hysterectomy, indications were: pelvic relaxation (30%), bleeding (28%), cervical dysplasia (21%), and uterine fibroma (only 7% of the cases) **(**9).

Another national study was carried out is VALUE, which describes the hysterectomies performed in Great Britain for 2 years (1994 and 1995), and which finds that the most frequent indication for hysterectomy is dysfunctional uterine bleeding (46%), followed by prolapse (19.79%), uterine fibroma (18.51%), endometriosis (7%), pelvic masses (4.23%), and other indications (4.47%) (16).

Querleu (9) believes that mobilization of the bladder is difficult in patients with C-section antecedents, regardless of the hysterectomy route and believes that C-section antecedents are not a contraindication for vaginal approach.

Although the VH is a routine surgical intervention, its costs and morbidity have a significant economic impact on health and social systems.

CONCLUSIONS

Our evaluations brought new evidence in supporting the vaginal hysterectomy with uterus removal in a short period of time, with minimal impact on the patient, with indication in benign tumoral pathology of the uterus, among which uterine fibromatosis associated with metrorrhagia, fibromatous uterus with cervical dysplasia, or fibromatous uterus associated with different degrees of uterine prolapse; it is a technique which uses a natural route, has a limited invasion and allows a rapid recovery of the patients.

In all cases, we took into consideration the onset of surgical menopause, which asks for prevention of emotional and sexual disorders, as well as disorders of other functions.

NEWS

IMMUNOSUPPRESSIVE THERAPIES FOR IGA NEPHROPATHY: A CONTINUOUS CHALLENGE

Immunoglobulin (Ig) A leads to end-stage renal failure in a significant proportion of patients. Immunosuppressive therapy, including steroids, is widely used to induce disease remission; however, it can cause serious side effects and therefore their use must be reduced. In this study the authors included pacients younger than 70 years, diagnosed with IgA nephropathy by renal biopsy; they had tonsillectomy. They were divided into two groups: Group A who's treatment was a single-course steroid pulse combined with mizoribine and Group B who received a three-course steroid pulse. In both groups, proteinuria decreased significantly after treatment. The glomerular filtration estimation rate (eGFR) increased after treatment in Group A, and tended to decrease in Group B. Group A also had a higher preservation of eGFR. In the **conclusion**, single-course steroid pulse therapy combined with mizoribine was considered to be superior with a protective renal effect in IgA nephropathy (Kaneko T, Arai M, Ikeda M et al. Comparison of immunosuppressive therapies for IgA nephropathy after tonsillectomy: three-course versus one-course steroid pulse combined with mizoribine. *Int Urol Nephrol*. 2015;47(11):1823-1830).

COMPARASIONS BETWEEN THE NON-PROLIFERATIVE AND PROLIFERATIVE THERAPY IN FIBROCYSTIC MASTOSIS (Abstract) **Aim**: Fibrocystic mastosis (FCM) is the most frequent benign breast lesion. Most treatments for fibrocystic mastosis are: hormonl, with beneficial results and non-hormonal, with fluctuating results. **Material and methods:** A number of 210 cases were studied, which were divided into 7 groups. The study lasted for 9 months and it was carried out on the basis of a personal examination sheet. The following were monitored: age groups, mastodynia, reducing breast nodules, a significant reduction in the volume of the mastosic cysts, reducion of the fibrous tissue, medication tolerance. **Results**: Mastodynia has declined by 90% in the cases treated with Tamoxifen and Danazol, by 70% in the case of Lynestrenol and Bromocriptine, by 50% in the 15 patients who were given Utrogestan. Knowing the advantages and disadvantages of drugs (contraindications, side effects), age category, breast pain reduction, antiproliferative activity, tolerability, relapse allow us to assess the benefit-risk. Even in those circumstances that remained incompletely clarified for objective reasons, related to the inaccurate/incorrect reporting by the patients, there is a significant difference ($p < 0.05$) between the frequency of relapses following the treatment with Tamoxifen and the other categories of drugs who were administered. **Conclusions:** Our study shows that in the groups that were administered Logest, Utrogestan and Bromocriptine, only antalgic effects were achieved (disappearance or only decrease of mastodynia) and no anti-proliferative effects were obtained. Basically, hormone treatment should be made based on a histopathological examination. **Keywords**: BENIGN BREAST DISEASE, PROLIFERATIVE, MASTOSIS.

Histopathologically, the fibrocystic mastosis (FCM) is defined as all the dystrophic changes in the breast tissue, the gathering under the form of fibrosis of the epithelial, cystic, metaplasic and hiperplasic modifications. The disease classification is different; the French authors consider it as mammary distrophy: fibrocystic mastosis (FCM), while the American authors consider it as a benign breast disease (benign breast disease). There is no current consensus on the content of this notion.

Both the diagnosis and the treatment of the benign breast diseases remain a challenge, and the indication for surgery is not clearly defined.

Any of the 3 categories of histopathological lesions has a different risk with regard to the possibility of occurrence of the breast cancer in the next 15 years, so that the non-proliferative do not increase the risk of a breast cancer, even if there is a family history of breast cancer, the proliferative lesions without epithelial atypia are risk around 2 for the appearance of a breast cancer, taking into account the associated epidemiological factors (1).

In order to assess the therapeutic value of a medicine we must take into account the risk/benefit ratio, and the risk is determined according to the contra-indications and adverse side effects(8).

Hormonal treatments are justified by hormonally dependent character, and possibly regressive, of the parenchymatous breast proliferations: cysts, apocrine metaplasia, ductal epithelial hyperplasia (epiteliosis), lobular epithelial hyperplasia (adenosis) (7).

For some drugs with hormonal action it has been demonstrated that they have an anti-proliferative activity, e.g.: Lynestrenol (which is a norsteroid), Tamoxifen and Danazol.

Cupceancu reported that 48 women with benign breast disease (BBD) were treated with Tamoxifen + Lynestrenol, and that the combination of these medicines has reduced substantially the size of adenomas, fibroadenomas, cysts and dysplastic lesions. Thus it was showed that Tamoxifen also had an antiproliferative action (2). Hurst et al. (3) argued that Tamoxifen produces significant regression of the breast cysts. Viviani et al (4) in the study "Ultrasound evaluation of the volume of breast fibroadenoma in women treated with Tamoxifen" conclud that this drug significantly reduces the volume of fibroadenoma when administered for 50 days at a dose of 20 mg per day.

Tan Chiu et al. (5) stated that, in 1998, the National Surgical Adjuvant Breast and Bowel Project had demonstrated that the treatment with Tamoxifen reduces the incidence of noninvasive and invasive breast cancer in the woman at high risk for this disease (thus Tamoxifen is recognized as having a prevention effect on the breast cancer).

The same authors had found that Tamoxifen reduced not only the risk of noninvasive and invasive breast cancer, but it also reduced the risk of benign breast disease relapses (BBD) and morbidity and the costs of repeated diagnoses and treatments that are associated with them. Thus, Tamoxifen is recognized as having a prevention action of the BBD relapses, including FCM.

Pricop et al. (6) states that Danazol can accomplish the disappearance of the cysts smaller than one inch in diameter, but that doesn't seem to diminish the fibrous tissue. Le Franc et al. (1990) specifies that, for the objective amelioration of the FCM "tumour plaques", 6 months are required and these results are not superior to those who followed a treatment with progestagens or with birth control pills, with progestagen predominance.

On the other hand, progestagens and bromocriptine are effective in the treatment of mastodynia (especially in cyclical mastalgia) and, to some extent, in fighting against breast nodes.

Currently there is no encoding in the use of these broad categories of hormonal medications: oral contraceptives, progestagens (Utrogestan), norsteroids (Lynestrenol), antiprolactinics (Bromocriptine), antigonadotrope drugs (Danazol, LHRH

agonists) and antiestrogens (Tamoxifen).

However, in the literature (1) it was mentioned that, because of the adverse side effects of the norsteroids, in practice it is recommended to start preferably with progesterone, locally and/or general, and in the event of inefficiency to resort to other treatments, first the norsteroids (Lynestrenol), thenn Danazol or antiestrogens (Tamoxifen).

MATERIAL AND METHODS

A number of 210 cases were studied, which were divided into 7 groups. The study lasted for 9 months and it was carried out on the basis of a personal examination sheet (fig. 1).

The data collected as study material and considered refer to: the total number of cases under investigation and diagnosed with fibrocystic mastosis, the division of cases into age groups, admission reasons, clinical examination, pathological personal history of clinical relevance for the basic disease (main diagnosis), family history relevant for the basic disease, anatomo-pathological diagnosis, the treatment followed.

The local administration of Diclofenac gel in the first 10 days after menstruation has been justified by the chronic inflammatory process due to the breaking up of the cysts and the release of their contents in the surrounding stroma.

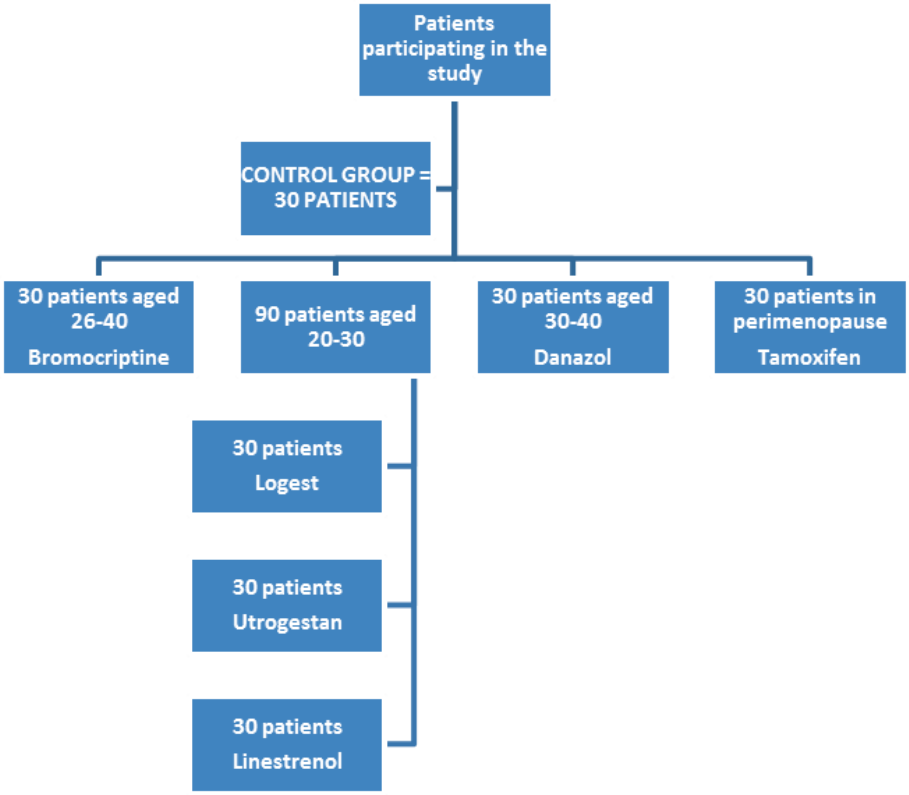

Fig. 1. Structure according to categories of patients included in the study

In 6 of the lots (of 30 patients each) a local background treatment with diclofenac gel and progestogel. Lot 7 was made of patients who refused any treatment (control group).

Each of the 6 groups were given, in addition to diclofenac gel and progestogel, one of the following drugs: Logest- 21 cp per month, 6 months; Utrogestan 10 days per month, 6 months; Lynestrenol 10 days per month, 3-6 months; Bromocriptine (parlodel), 3 months; Danazol 200 mg/day - 3 months; Tamoxifen 6 months. We have not had cases with LHRH (gonadotropin releasing hormone) treatment.

They were studied under this treatment, at first, after 3 months and after 6 months, by imaging (ultrasound and mammography) and FNAC - fine-needle aspiration cytology (sporadically). Further on, we studied, at 9 months, the possible relapses and some histo-pathological examinations after these hormonal treatments.

The following were monitored: age groups, mastodynia, reducing breast nodules, a significant reduction in the volume of the mastosic cysts (which has been made by ultrasonography), reducion of the fibrous tissue, medication tolerance (frequency of relapses; risk/benefit ratio).

RESULTS

The FCM incidence is estimated in over 60% of women. It is frequent in women of ages between 30 and 60 years. For the data in our study, we calculated the FCM incidence signalled in relevant personal history to 20%; obviously, values were lower after referring to the entire batch under study, namely 6.68%.

Most part of the patients who attended our unit came from the urban environment (66.9%), and the ones from the rural environment were only 1/3 of the reported cases (33.1%).

Depending on the age of the lot, the women aged between 20-30 years were administered, in an equal number of cases, namely 30 cases (out of a total of 90 cases), Logest or Utrogestan or Lynestrenol , and the women aged 26-40, i.e. 30 cases, were given Bromocriptine. In other 30 cases, the women aged between 30-40, were given Danazol, and Tamoxifen was administered to 30 patients placed in perimenopause, although Tamoxifen is recommended as the first-line treatment.

Mastodynia has declined by 90% in the cases treated with Tamoxifen (27 patients) and Danazol (27 patients), by 70% in the case of Lynestrenol (21 patients) and Bromocriptine (21 patients), by 50% in the 15 patients who were given Utrogestan. In only 9 patients (30%), mastodynia was reduced in case of the treatment with Logest.

Another apect that was had in view was the reduction of the nodules. This reduction was present in 80% of cases treated with Tamoxifen and Danazol in 50% of the cases treated with Lynestrenol, 40% of the cases receiving Bromocriptine, 30% of the cases treated with Utrogestan and 20% of those treated with Logest.

The volume of mastosic cysts, according to the diameter of the cysts measured by ultrasound, was reduced in a percentage of 80% in the cases treated with Tamoxifen and in those treated with Danazol. In the case of the treatment with Tamoxifen, the volume of the mastosic cysts was reduced by 50% in the case of the cysts with the diameter greater than 1 cm and reduced in full in the case of the cysts with a diameter smaller than 1 cm. As for the Brocriptine and Logest, in none of the cases there has been a reduction of the volume of the mas-

tosic cysts.

According to the reduction of the fibrous tissue under therapy, the influences (actions) of the physiotherapy treatments (ultra-rays, ultrasound, etc.) on the fibrous tissue have not been studied. No hormonal drug has reduced the fibrous tissue. This is an argument for the usefulness (or necessity) to prevent the formation of the fibrous tissue, via the early treatment of the fibrocystic mastosis. The fibrous tissue is not hormone-dependent.

The case distribution according to the tolerability of the treatment was of 100% in the cases treated with Logest and Utrogestan, with a very good degree of tolerability. The degree of tolerability is good in the cases treated with the other treatments.

In terms of the frequency of relapses, the results we obtained were as follows: for patients receiving treatment with Logest, Progestogel, Utrogestan (Duphaston) or Bromocriptine, the frequency of relapses was of 70%. In the case of the treatment with Lynestrenol, we noticed a presence of relapses in 50% of the cases. Danazol caused a lower frequency of relapses in only 30% of the cases. The best results were achieved following the treatment with Tamoxifen for which relapses were mentioned in only 20% of the cases.

After the experience of Pricop et al.-2003 and of Tan Chiu et al, 2003, and also after our personal experience, the risk-benefit ratio is most favorably inclined towards Tamoxifen, that does not represent any hazard at the dose of 10 mg/day (3 months).

DISCUSSION

Knowing the advantages and disadvantages of drugs (contraindications, side effects), age category, breast pain reduction, antiproliferative activity, tolerability, relapse allow us to assess the benefit-risk.

In order to assess the risk/benefit ratio, we must know the risks, which are represented by the contraindications and adverse side reactions.

It is known that if a drug, at a specific dose, has a favorable action in a certain direction but it has adverse side effects of high intensity, the risk/benefit ratio is low and the use of such drug is more limited.

In these cases the therapeutic strategy means associating more drugs with the same desired beneficial action, but with different adverse side effects (which are not cumulative). In this way drugs can be administered in low doses because the beneficial effects are cumulative and the adverse side effects are different and of low intensity, and they are not cumulative because they are not identical. The combination of drugs that have the same adverse side effects or similar side effects is contraindicated, as they will be cumulative.

Therefore, in treating FCM, the association of Lynestrenol with Danazol is not indicated because they have virilising side effects and adverse effects (on the liver) in liver diseases. The association of Danazol and Tamoxifen is not found in the literature, likely because both can cause prolonged amenorrhoea (though perhaps not by the same mechanism) and due to weight gain (fluid retention).

Moreover, except for the combination of Progestogel with an oral progestagen, and the combinaton of Tamoxifen with Lynestrenol (2), we have not found in the literature any other drug combination for the treatment of FCM.

Since the administration of Progestogel is relatively efficient and the most anodyne, we maintained the administration preceded

by Diclofenac gel in all cases, whether we associated it to Utrogestan, Lynestrenol, Bromocriptine, Danazol or Tamoxifen (the latter two at the minimum effective dose to reduce the adverse side effects that limit their use).

Another problem is the main drug choice based on age. Thus, in young patients, progestins were used, like simple Progestogel or combined with Utrogestan, or in rebel cases, Utrogestan was replaced by Lynestrenol (norsteroid progestagen).

Over time, the mastosic cysts can increase in size and number, accompanied by fibrous elements whose provenance is insufficiently known. This is why in our series the treatment, in all the groups, maintains the local use of Diclofenac gel.

In patients over 30-35 years old and in premenopause patients we used Danazol or Tamoxifen. By administrating Utrogestan, Bromocriptine, Danazol, Tamoxifen, under the same conditions, we have created the opportunity to compare their effectiveness.

The fibrous tissue prevents the access of drugs to the mastosic cysts and it is more resistant to treatment, if not even far from any effect, therefore much more effective drugs are necessary (even if they have more important adverse side effects) (9).

Even in those circumstances that remained incompletely clarified for objective reasons, related to the inaccurate/incorrect reporting by the patients, there is a significant difference ($p < 0.05$) between the frequency of relapses following the treatment with Tamoxifen and the other categories of drugs who were administered.

The intent of obtaining histopathological results after the hormonal treatments administered for 3-6 months has not been achieved because the patients refused the biopsy and even the fine needle aspiration cytopunction (10).

Following these results, there is the issue of choosing, between these drugs, the most beneficial hormonal treatment, taking into account the benefit/risk ratio, or possibly the individualization of these treatments.

CONCLUSIONS

Our study shows that in the groups that were administered Logest, Utrogestan and Bromocriptine, only antalgic effects were achieved (disappearance or only decrease of mastodynia) and no anti-proliferative effects were obtained.

In correspondence to the literature data, we found that, in a number of cases, relapse occurred.

In the group under Bromocriptine, tolerability was average, while it was very good in the other two groups. In the groups that were administered Lynestrenol, Danazol and Tamoxifen anti-proliferative effects were achieved (beside the disappearance of mastodynia).

Therefore, under Lynestrenol, the nodules (tumour plaques) disappeared, along with some of the mastosic cysts under 1 cm, and the mastosic cysts larger than 1 cm reduced their size. Tolerability was good.

Under Danazol, the nodules (tumor plaques) disappeared, along with many of the mastosic cysts under 1 cm, and the mastosic cysts larger than 1 cm reduced their size. Tolerability was average.

Under Tamoxifen, the nodules (tumor plaques) disappeared, along with many of the mastosic cysts under 1 cm, and the mastosic cysts larger than 1 cm reduced their size. Tolerability was good.

Further on, we found that after the treatment with Tamoxifen the relapses were the fewest.

Before beginning the hormone treatment for FCM, malignancy should be excluded, as we must not forget (1) that a malignant lesion can simulate a benign one.

According to our personal experience, and to the experience of Pricop et al. (6) and Tan Chiu et al. (5), the most favorable benefit-risk ratio refers to tamoxifen, which in the dose of 10 mg/day (3 months) is not dangerous for the patient.

ATYPICAL FEMORAL FRACTURES AFTER LONG-TERM BISPHOSPHONATES THERAPY: CASE REPORT. (Abstract). We present a 77 years-old woman with no history of trauma, or associated with low-energy trauma, admitted to our clinic after three weeks of a left femoral fracture threated in Orthopedic Clinic. The patient was in treatment with bisphosphonates over 10 years for osteoporosis. **Discussion and conclusions:** The causal relationship between prolonged bisphosphonate use and the occurrence of atypical femoral fractures (AFF) has not yet been established. For the patient at high risk of fracture, it may be beneficial to continue bisphosphonate treatment beyond five years. The absolute risk of atypical femoral fractures is low (about 100 cases per 100,000 person-years among long-term users). For most people with osteoporosis, the proven fragility-fracture risk-reduction benefits of bisphosphonates outweigh the risks of AFF. **Keywords:** ATYPICAL FEMORAL FRACTURE; BISPHOSPHONATES; OSTEOPOROSIS.

Bisphosphonates are a class of widely prescribed drugs that are proven to be effective in reducing common bone fractures in people with osteoporosis and those at a high risk of fractures. Concern among doctors and patients has arisen following recent media reports that cite a possible association between unusual and unexpected (atypical) fractures of the upper thigh bone and bisphosphonate use. Recent published studies (1) examining this potential association are conflicting regarding the existence and strength of this association. Bisphosphonate-related proximal femoral fractures are an example of insufficiency fractures, although the direct causative link remains somewhat controversial (1). According to a task force report from the American Society for Bone and Mineral Research (ASBMR), this relationship has not yet been shown to be causal. All current evidence indicates that atypical femoral fractures (AFF) represent a rare subset of subtrochanteric and femoral shaft fractures (2). Femoral shaft fractures had an incidence of 2.5 to 9.9 per 100,000 person-years, but 75% occurred with high-energy trauma and the majority were comminuted and had a spiral configuration (3). A review of radiographs by

Schilcher et al. (4) found an incidence of 55 atypical fractures per 100,000 person-years among bisphosphonate users compared with 0.9 per 100,000 person-years among those with no bisphosphonate use. Characteristics of AFF are: a transverse, noncomminuted fracture at the subtrochanteric or femoral shaft region with a medial cortical spike at the fracture area. Other features include prodromal pain and generalized thickening of the femoral cortices on radiographs. For the clear criteria to define atypical femoral fractures, the ASBMR task force established major and minor features for both complete and incomplete atypical fractures of the femur (2). All of the major features should be present to designate a fracture as atypical: No history of trauma, or associated with low-energy trauma; Fracture located anywhere from distal to the lesser trochanter to proximal to the supracondylar area; Transverse or short oblique fracture configuration; Noncomminuted fracture; Medial spike in complete fractures, incomplete fractures involve only the lateral cortex. The minor features have also been described in association with atypical femoral fractures, but they are not required for diagnosis. Localized periosteal thickening of the lateral cortex; Generalized thickening of the femoral cortices; Prodromal symptoms; May be associated with bilateral fractures or symptoms; Evidence of delayed fracture-healing; Comorbid conditions or the use of some medications.

CASE REPORT

A 77 years-old woman, weight 62 kg and height 1.58 was admitted to Endocrinology clinic after three weeks of a left femur fracture in mid-thigh, threated in Orthopedic Clinic (fig. 1).

Fig. 1. The patient after orthopedic surgery

Orthopedic Surgery underwent the closed reduction and internal fixation with intra medullary hip screw (fig.2 b). The patient was in our clinical observation since 1983 for hypothyroidism after thyroidectomy in treatment with 100 mcg LT4. In 2002 the patient was diagnosed with osteoporosis following the DXA examination. The bone mineral density (BMD), measured by dual-energy X-ray absorptiometry (DXA) showed T-score at total lumbar spine: - 4.0, total hip: -2.1, and left femur neck: -3.0. 25-OHD3 level varied between 17.69 ng/mL and 5.54 ng/mL (normal>30 ng/mL). Thyroid Stimulating Hormone, thyroxin and triiodothyronine level was normal. Has been established treatment with risedronicum acidum 35 mg/week (Actonel), Alfacalcidol 1 mcg/day and calcium 1000 mg/day. Annual DXA-BMD shows a slight increase the density of the bone; patient medical treatment has been changed in zoledronicum acidum and then on alendronicum acidum.

In 2013 there is a decrease of BMD DXA, but our patient require the continuation of the therapy with a drug with large intervals administration .Ibandronicum acidum has been recommended. After surgical orthopedic treatment were discussed with the patient, the risks and benefits of each option. The new anteosteoporotic treatment was strontium ranelate in association with Alfacalcidol and calcium. An association between bisphosphonate long-term use and the occurrence of AFF has been suggested. This diagnostic has been supported and by the x-ray. The radiographic features of an atypical femoral fracture: femoral shaft region (fig. 2a), transverse fracture configurations, absence of comminution, a medial spike, localized periosteal thickening of the lateral cortex, and generalized thickening of the femoral cortices.

a b c

Fig. 2 a. transverse fracture configurations, absence of commination, a medial spike, localized periosteal thickening of the lateral cortex, and generalized thickening of the femoral cortices. b. Post-operative radiograph after surgical fixation. c. Post-operative radiograph after 3 month.

DISCUSSION

AFF have been associated with various factors, including: bilateral fractures, prodromal pain, the use of glucocorticoids and proton pump inhibitors, delayed fracture-healing, presence of rheumatoid arthritis or diabetes mellitus as well as vitamin-D3 deficiencies (5, 6). A post hoc analysis of data from three randomized trials of bisphosphonates for postmenopausal osteoporosis identified twelve subtrochanteric or diaphyseal femoral fractures in ten of the 14,195 study participants, yielding a rate of 23 per 100,000 person-years. Reanalysis of the data in three major randomized controlled trials showed no statistically significant increase in the risk of subtrochanteric femoral fracture in patients treated with bisphosphonates for as long as ten years (2). Given the mixture of results and the different methodologies used in these studies, it is difficult to demonstrate consisten-

cy of this association. Studies (7) have shown an increased risk of atypical femoral fractures in patients taking bisphosphonates for five or more years, suggesting a dose-response relationship. The ASBMR task force reported an incidence of 2 per 100,000 cases per year after two years of bisphosphonate use, increasing to 78 per 100,000 cases per year after eight years of use. Management of patients with AFF: Stop bisphosphonates. Consider an anabolic agent such as teriparatide. Calcium and vitamin-D supplementation (6). Identify any underlying metabolic bone diseases by laboratory investigations such as serum calcium, phosphate, 25-hydroxyvitamin D, intact parathyroid hormone, thyroid-stimulating hormone, bone turnover markers, and 24-hour urine calcium. Intramedullary nailing is the preferred method of fixation. Assess the contralateral femur. If the patient has an incomplete fracture, a period of conservative therapy may be considered. Five of six patients had progression of the lesion to complete fracture at a mean of ten months. Management of patients with prolonged bisphosphonate therapy: If a patient sustains an atypical femoral fracture, bisphosphonates must be stopped. Once administered, bisphosphonates accumulate in the bone and continue to be released for months or years after treatment is discontinued. Regarding over suppression of bone turnover with prolonged bisphosphonate therapy, it is recommended that osteoporosis treatment with bisphosphonates be stopped after a period of five years to provide patients a so-called ‘‘drug holiday’’. Park-Wyllie et al. performed a nested case-control study to explore the association between bisphosphonate use and femoral fractures, and they reported that bisphosphonates treatment of more than five years was associated with an increased risk of atypical subtrochanteric or femoral shaft fractures (7). Therefore, it may be appropriate to consider a drug holiday in patients with a cumulative duration of bisphosphonate treatment of more than five years. The absolute risk of atypical femoral fractures is low (3.2 to 50 cases per 100,000 person-years among short-term bisphosphonate users and about 100 cases per 100,000 person-years among long-term users). Consequently, for most people with osteoporosis, the proven fragility-fracture risk-reduction benefits of bisphosphonates outweigh the risks of AFF (8).

CONCLUSIONS

Patient confirms the risk of atypical femoral fractures in prolonged bisphosphonate therapy, but let us not forgets benefits of bisphosphonates.

NEWS

SHED - BASIC STRUCTURE FOR STEM CELL RESEARCH

Stem cells are defined as clonogenic cells capable of both self-renewal and multi lineage differentiation. Stem cells have been differentiated from variety of body parts and have shown great promise in the management of variety of diseases in medicine. Recently, stem cells have been isolated and grown from: Human permanent dental pulp tissue stem cells (DPSCs), Stem cells from human exfoliated deciduous teeth (SHEDs), and Periodontal ligament apical papilla of immature teeth (PDLSCs). If we have in hand population of stem cells that reproducibly reform bone, cementum, dentin, and perhaps even periodontal ligament; it is possible to envision complete restoration of the hard tissues in the oral cavity using the patient's own cells, thereby avoiding issues of histocompatability. This would be a more biological approach rather mere mechanical one. It has been reported that the stem cells obtained from the above said sources can generate dentin like tissue both in vitro and in vivo studies in animals. In addition transplanted skeletal or dental stem cells have the potential to "rephrase" repair craniofacial defects and repair/regenerate teeth. This review study showed that stem cells from human exfoliated deciduous teeth are distinct from dental pulp stem cells by virtue of their proliferation rate, increased cell population doublings and osteoinductive capacity in vivo. It also demonstrated that human exfoliated deciduous teeth stem cells may not be a single-cell type, may well be a heterogenous population of cells from the pulp (Kashyap R. SHED - Basic Structure for Stem Cell Research. *Journal of Clinical and Diagnostic Research*. 2015 Mar, Vol-9(3): 7-9).

HEAD CIRCUMFERENCE REFERENCES FOR SCHOOL AGE CHILDREN IN WESTERN ROMANIA (Abstract)**: Aims:** To provide head circumference references for school-aged children in western Romania, and compare them with references from other European countries. **Methods:** A total of 2742 children, aged 6-19 years, from Timis county, were examined by medical students, between February 2010-June 2011. Head circumference references were constructed by Cole's LMS method with LMSChartMaker software. The Romanian 3rd, 50th and 97th percentiles for head circumference were compared with recent references from Belgium and Germany. **Results:** Generally, boys show significantly larger head circumference compared to girls at any age. The head circumference increments between 6 and 19 years are < 1 cm/year. Head circumference increments decrease in increasing age of the children. In girls, adult head circumference is reached at the age of 16 years, whereas head circumference growth continues, in boys, slowly until 18 years. The comparison of Romanian head percentiles with those from Belgium and Germany revealed a smaller head circumference in Romanian children (both girls and boys). **Conclusions:** Comparing head circumference references from Romania to those from Germany and Belgium, we found lower median head circumference in Romanian boys and girls, that could be explained by a taller stature of boys and girls in Germany and Belgium compared to Romania. **Keywords**: HEAD CIRCUMFERENCE, CHILDREN, PERCENTILES, WESTERN ROMANIA.

Head circumference (HC) measuring and head growth evaluation constitute the most simple, inexpensive and readily available tools to assess the development of the central nervous system and identify neonates at risk of neurodevelopmental disorders (1). Furthermore, head circumference is an accurate indication of abnormal brain volume in later age, used mainly to screen for macro- or microcephaly and their various underlying pathologies (2). With knowledge of age-dependent head circumference-to-brain volume relationship, head circumference (in relation to age) can be an accurate indication of normalcy of brain size and growth in a clinical setting (3). Several studies also reported a direct relation between head size and intelligence, learning, nutritional status and brain development (4–6). Moreover, some studies suggest a relation between

head circumference and autism (7,8). A genetic study showed suggestive evidence of association between head circumference and adult intracranial volume, Parkinson's disease and other neurodegenerative diseases, indicating that a common genetic variant in the chromosome 17q21 region might link early brain growth with neurological disease in later life (9).

As research progresses, the clinical impact of HC measurements may become even more important. However, normative data for head circumference over the childhood and adolescence period are lacking for a Romanian population.

Therefore, the aim of this paper was to provide head circumference references for Romanian school-aged children and to compare them with references from other European countries.

MATERIAL AND METHODS

Studied population:

Timis is the largest county in the west part of Romania. According to the National Institute of Statistics, Timis county has an area of 8,697 km^2.(10) The city of Timisoara is the largest in the county. When the present study started, in 2010, in Timis there were 67146 children attending school. We randomly chose 5 schools from Timisoara (enrolling 5676 students) to collect data for this study. The response rate was 50 %. Some students failed to be measured due to various reasons, including school absenteeism and conflicting school activities/responsibilities (certain classes were not interrupted for the measurements). A total of 2742 children, aged 6-19 years were examined by medical students, in the period February 2010 - June 2011.

Exclusion criteria:

Exclusion criteria were: genetic syndromes, cancer, or other chronic disease influencing growth, including children diagnosed with growth hormone deficiency, diseases affecting bone metabolism, cystic fibrosis, renal disease, congenital adrenal hyperplasia, and congenital heart defect with impairment of physical fitness.

Anthropometric techniques:

Prior to each data collection round, all examiners were trained in taking accurate measurements, according to international measurement techniques (11). Each child underwent anthropometric assessments (height, weight and head circumference) that were carried out during one day session. Head circumference was measured with a non-stretchable glass fiber tape measurer. The tape measurer was placed in a straight line from the supra-orbital position to the largest protuberance at the back of the head. Caution was taken to clear the auricles before measuring. The head circumference was recorded to the last completed millimeter. The age of children was rounded down when child's age was years and 1-6 months and rounded up when the age was years and 7-12 months.

Statistical analysis

Growth reference construction

Data were cleaned and validated with SPSS, PC program (version 19.0 - SPSS Inc., USA). Outliers were checked carefully for possible mistakes of data recording. None of the outliers was considered to be biologically implausible. Descriptive statistics were run on all the variables. Statistical significance was considered when $p<0.05$. Growth references for head circumference were constructed with the lambda, mu, sigma (LMS) method and LMSChartMaker Light software (12). The LMS method (lambda, mu, sigma) summarizes the

changing distribution by three curves representing the median (mu), coefficient of variation (sigma) and skewness (lambda), the latter expressed as a Box-Cox power (13). We decided to fit the following percentiles: 3rd, 15th, 25th, 50th, 75th, 85th and 97th, for head circumference in relation to age. We made this choice in order to enable comparison with head circumference references from other European countries.

References for height, weight and body mass index for western Romania, from the collected data are presented in another article (14).

Comparison with references from other countries for head circumference

Comparison with the chosen head circumference references was based on comparability with regard to statistical methods of constructing the reference. The 3rd, 50th and 97th percentile for head circumference were selected and compared with the data from: 2009 References for growth and pubertal development from birth to 21 years in Flanders, Belgium (15) and 2011 German head circumference references for infants, children and adolescents - KiGGS study (16).

Ethical considerations:

Because of the noninvasive nature of the protocol, consisting only of measurements that are a routine for school examinations (height, weight, head circumference), we used a passive consent or opt out method. Parents were fully informed about all study procedures through a school information meeting. Parents who refused the participation communicated this tot the school principal. Prior to the measurement, the child was also asked whether s/he agrees with it. The children's names were not included in the electronic data files. Examiners ensured the basic principles of confidentiality, privacy and objectivity throughout the process. The children were measured in a private room, boys and girls separately. The approval of the University's Ethical Advisory Commission is in accordance with the Helsinki Declaration.

RESULTS

Demographics

After applying the exclusion criteria, 12 children were taken out of the database because they had either growth disturbances as a result of a primary disease (malignancies, endocrine diseases, etc.) or as a consequence of treatment (growth hormone, steroids). We also excluded 9 children that were older than 19 years. A total of 2742 children, aged 6-19 years were examined between February 2010-June 2011, from 5 public schools in Timisoara. The study evaluated 1071 boys (39.1%) and 1671 girls (60.9%), with a male/female ratio of 1:1.5. The mean values and SDs for body weight, height and head circumference in relation to age are shown in tab. I. The mean age was 12.99 years (SD=3.49); with a symmetric distribution (skewness = -0.098; kurtosis= -1.075).

The data showed a strong Pearson correlation between head circumference and height (r=0.583, p=0.000) and an even stronger correlation with age (r=0.815, p=0.000).

Smoothed percentiles for head circumference in centimeters, constructed with the LMS method, for boys and girls separately, are shown in tab. II and tab. III, respectively.

Graphical representation of smoothed percentiles for head circumference in centimeters, constructed with the LMS method, for boys and girls separately, are shown in figure 1 and 2, respectively.

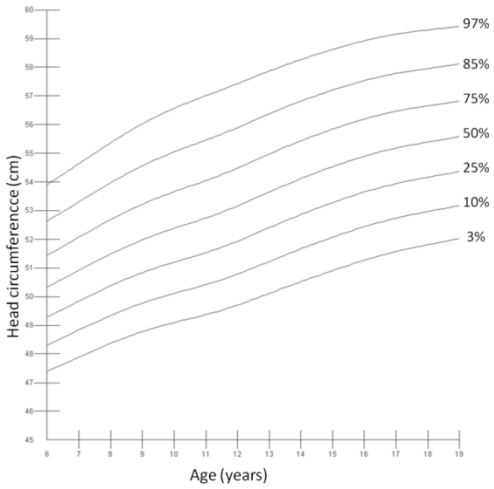

Fig. 1. Head circumference graph percentile for boys age 6-19 years

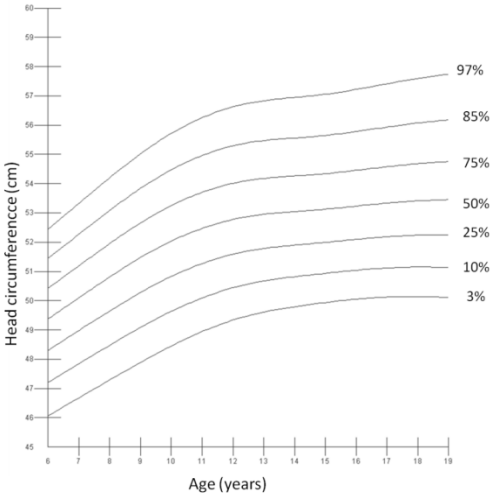

Fig. 2. Head circumference graph percentile for girls age 6-19 years

The head circumference increments between 6 and 19 years are < 1 cm/year. Head circumference increments decrease with older age from 0.96 to 0.01cm at age 18 years. Between ages 9 and 11 years in boys, the annual increments in head circumference increase again from 0.35 to 0.49 cm and thereafter decelerate gradually until age 17 years. In girls, the decrease in increment is progressive with older age, with increments < 0.2 cm after 9 years. From age 16 years onwards, the head circumference increments are still measurable in boys with at least 0.3 cm per year, but not in girls (<0.1 cm). At 19 years age, a median head circumference of 55.4 cm in boys and 53.5 cm in girls is attained. In general, boys show significantly larger head circumference compared to girls at any age.

For the purpose of comparison, we ana-

lyzed the 3rd, 50th and 97th percentile for head circumference for Romanian (presented data), German KiGGS study (15) and Belgian (14) children age 6-19 years, as shown in figures 3., for boys and in figure 4., for girls.

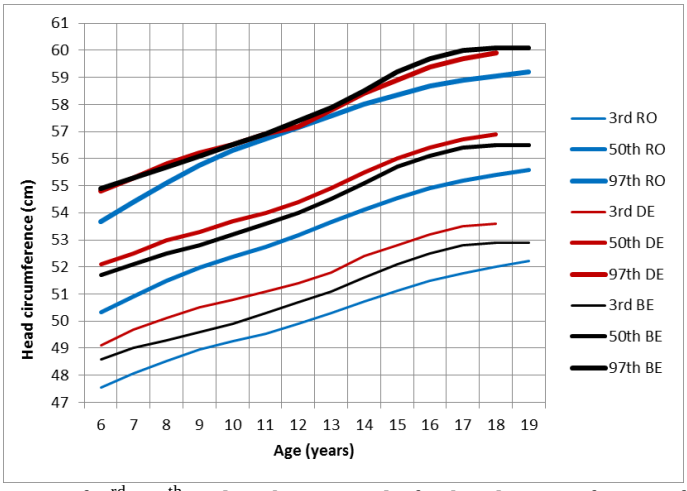

Fig. 3. Comparison of 3rd, 50th and 97th percentile for head circumference for boys age 6-19 years from Romania – in blue, Germany in red (16) and Belgium in black (15)

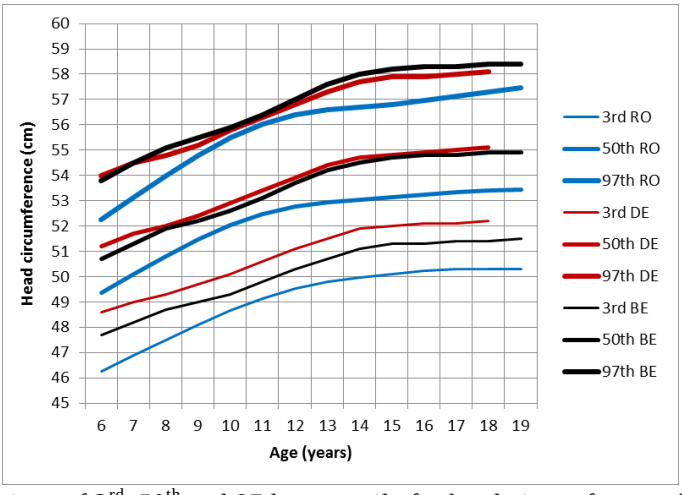

Fig. 4. Comparison of 3rd, 50th and 97th percentile for head circumference for girls age 6-19 years from Romania in blue, Germany in red (16) and Belgium – in black (15).

The comparison of 3rd, 50th and 97th percentile for head circumference in, both, boys and girls, age 6-19 years from Romania, Germany (16) and Belgium (15), shows that Romanian children have a smaller head circumference when compared to their peers in Germany and Belgium. Mean difference between German and Romanian head circumference in children is 1.4 cm for boys (2,56% of median

German head circumference) and 1.4 cm girls (2,61% of median German head circumference), while between Belgian and Romanian head circumference it is 1cm (1,84% of median Belgian head circumference) in boys and 1.2 cm in girls (2.24% of median Belgian head circumference). Greater mean differences (>1cm) in head circumference are seen between the Romanian compared to German and Belgian children especially after the age of 14 years in boys and after 13 years in girls.

Considering that the differences in head circumference in children between countries could be due to different genetics, we looked at height differences between children from these countries. Height data from Belgian study (15) show that Belgian boys are taller that Romanian peers with an average of 1 cm, while Belgian girls are taller with 1.2 cm in average, when compared with Romanian girls (14). When correlating the difference in height with difference in head circumference between Belgian and Romanian children, data revealed a strong Pearson correlation for girls ($r=0.834$, $p=0.000$) and poor correlation for boys ($r=0.291$, $p=0.000$).

DISCUSSION

The sex-specific head circumference-for-age percentiles presented here are the first reference values from a sample of Romanian children, for the age range 6 through 19 years. In general, boys show significantly larger head circumference compared to girls at any age. As expected, the head circumference increments between 6 and 19 years are small (< 1 cm/year) (15,16). Head circumference increments decrease with growing age. In girls, adult head circumference is reached at the age of 16 years, whereas head circumference growth continues, in boys, slowly until 18 years. This finding is consistent with previous studies (15,17,18). However, a study from the Netherlands showed that head circumference marginally increases until age 21 years in boys (19).

After 6 years of age until age 9 years, in boys, head circumference growth occurs in relatively constant increments per year, however, a growth spurt in head circumference follows, from 9 to 11 years and appears to be closely related to the puberty. Similar findings were published in the German KiGGS study (15) and a Japanese longitudinal study from birth to 15 years of age, who found an adolescent growth spurt in head size (20). However, in our study we did not detect similar findings for girls, but a steady decrease in head circumference increment after the age of 9 years.

The comparison of Romanian head percentiles with those from Belgium and Germany revealed a smaller head circumference in Romanian children (both boys and girls). The pattern of head size growth is particularly different in Romanian girls when compared with their peers from Germany and Belgium, showing the slowing of growth for the Romanian girls, after 13 years, when compared with the growth pattern of their peers. Considering that the differences between the 50th and the 3rd percentile, represent 6,11% of median head circumference, the difference between German, Belgian and Romanian peers (ranging from 1.8-2.6% of median head circumference) would represent approximately a 15 percentiles distance, that is significant. A plausible explanation for this discrepancy could be due to genetic factors. Height has a good correlation to head circumference (20). Therefore, we looked at height differences between populations and

found that Belgian boys and girls are taller than Romanian peers, with 1 cm, in average. However, observing correlation between differences in height and in head circumference we found inconclusive results: a good correlation for girls and poor correlation for boys. A clear conclusion could not be drawn regarding the relation between height and head circumference, thus, further studies might be needed.

Study limitations

The sample of children in this study is representative for the west part of Romania; however, it cannot be extended for the entire population of the country. Another limitation of the study is that it does not provide data from birth to 6 years age group. Head circumference can be influenced by multiple factors: gestational factors (such as, mother nutrition (22), socioeconomic status (4), period of gestation, iodine intake during pregnancy (23)), and genetic syndromes, or factors influencing puberty etc. These factors were not evaluated in this study.

The genetic background has a major role in determining both height and head circumference in a population; however, we did not investigate the ethnic background of the studied population. Results from the latest census of population, in 2011, in the Timisoara 81.4% are Romanian, 4.9% are Hungarians, 0.7% are Rroma, 0.2% are Ukrainians, 1.3% are Germans, 1.5% are Serbians and 10% have other ethnicity (10). Although, the genetics of these populations are different and have an impact on head circumference, the percent of different ethnicities is not high enough to influence the study results. Further studies are needed to elucidate the impact of ethnic background on head circumference.

CONCLUSION

The study shows sex specific head circumference-for-age references for a Romanian population, thus allowing a description of the head size growth from 6 to 19 years. Comparing references from Romania to those from Germany and Belgium, we found a significantly lower median head circumference in both Romanian boys and girls, that could be explained by a taller stature of boys and girls in Germany and Belgium compared to Romania. A more widespread study should be carried out by including children from different regions of Romania.

THE RELEVANCE OF SOME MOLECULAR MARKERS IN RECURRENT PANCREATIC CANCER: FOCUSING ON CA 19-9 AND CYTOKERATINS (Abstract). Lately it is generally believed that the incidence of pancreatic neoplasm has increased exponentially all over the world, and especially in the last decade, by even becoming the fifth cause of death by cancer. However, the vast majority of the patients present to the clinic in the advanced unresectable stages, while significant risk factors for pancreatic cancer are still insufficiently studied. In addition, when it comes to the recurrence of the pancreatic cancer, there are also many unknowns regarding the mechanisms and the factors which are implicated. In this way, in this mini-review we want it to make a concise description and analysis for the relevance of some molecular factors in recurrent pancreatic cancer, by mainly focusing on CA19-9 and cytokeratins, besides the other classical clinical factors which are relevant in the diagnostic of the pancreatic cancer recurrence. **Keywords:** RECURRENT PANCREATIC CANCER, MOLECULAR MARKERS, CA 19-9, CYTOKERATINS.

The incidence of pancreatic neoplasm has increased over the last years in many parts of the world, by becoming the fifth or even sixth cause of death by cancer in the Western countries. In fact, pancreatic ductal adenocarcinoma is the most common malignant disease of the pancreas, with the origin in the ductal epithelium. With an incidence of 10-11 per 100.000 inhabitants in the Western countries, it is one of the most aggressive human tumors (1).

In this way, in 2.000 there were diagnosed 216.400 new cases and 215.500 deaths caused by this disease worldwide, while in 2004 in the United States there were predicted 31.860 new cases and 31.270 deaths, which indicates that, due to a very low survival rate, the incidence and mortality are similar (2).

Moreover, the fatality rate correlated with the age varies between 3.1 and 20.8 per 100.000 inhabitants with a corresponding peak for the patients between 60 and 80 years (3).

Unfortunately, 95% of the patients present to the doctor in the advanced unresectable stages, and despite the fact that over the past few decades the development and

advance of the surgical methods and techniques have improved; only morbidity and hospital postoperative mortality are becoming better, without significant impact on survival.

Thus, the only way of establishing a diagnosis in the early stage, potentially curable, would be a rigorous anamnesis that would reveal the early symptoms to 'send' the patient to the doctor in the early stage.

Despite this, most of the classical studies carried out have not been able to identify the significant risk factors for pancreatic cancer, but several risk factors were described as being involved: smoking, chronic pancreatitis, diabetes mellitus, previous gastrectomy and exposure to radiation or chemicals such as chlorinated hydrocarbon based solvents (4-6).

However, despite the numerous studies about pancreas cancer, little is known about this issue. The resections for the cancer of pancreas have entered the therapeutic arsenal for 65 years, but despite the fact that hundreds of articles were written on this subject, there is no unanimity of opinion concerning the efficacy of resection. A number of authors have reported a 5 years survival rate of 30% or even 58%, being supportive of resection (7-9).

In addition, when it comes to the recurrence of the pancreatic cancer, there are also many unknowns regarding the mechanisms and the factors which are implicated. In this way, in this mini-review we want it to make a concise description and analysis for the importance of some molecular factors in recurrent pancreatic cancer, by mainly focusing on CA19-9 and cytokeratins, besides the other clinical factors which are relevant in the diagnostic of the pancreatic cancer recurrence, such as CT, PET, echography or MRI analysis, which of course are not relevant in this context.

FOCUSING ON CA19-9

In this way, CA 19-9 was described for the first time by Koprowski et al. and represents an associated tumoral tissue carbohydrate antigen found on the surface of many types of gastrointestinal tumoral cells. Moreover, Koprowski immunized colorectal cancer cell lines in mice and then isolated the CA 19-9 monoclonal antibodies from the splenocytes of the respective mice. Subsequent studies have shown that the antigen is normally present in salivary mucus and pancreatic exocrine juices, so that, although it originates from colorectal tumoral cell lines, is currently useful in the diagnosis, prognosis, evaluation and monitoring of patients with cancer of the pancreas (10-12).

Also, some researchers have tried to demonstrate the usefulness and efficiency of sequential determination in the dynamics of CA 19-9 in the serum of patients during the postoperative monitoring period. Probably this type studies was first carried out in 1986 at the National Cancer Institute, Bethesda, when the authors notified that patients who experienced a decrease in serum levels to normal values after the operation had a better survival rate than those in which the marker levels maintained at the same increased level. Also they have demonstrated that an increase in the levels of CA 19-9 > 95U/mL or four times its lowest value, immediately post operatory, represents a factor of prediction for the disease progression (13).

In addition, another study has shown that elevated serum level in the post operatory period precedes the occurrence of lesions detectable through CT or clinical examination, with 2 up to 9 months (14).

Also, Montgomery et al. had previously shown that periodic measurements of the CA 19-9 post-operatory level is the best predictor for the survival without recurrence period "disease free survival" and also for the total period of survival. His group also shown that patients in which the level of CA 19-9 returns to normal values for 3 to 6 months, have longer periods of overall survival and survival without relapses than those in which the level is remaining high (15).

Moreover, the same author noticed that the survival rate of the patients in which the post operatory level of CA 19-9 has been less than 180 U/mL at 1 and 3 months, was similar to that of the patients in which the CA 19-9 level returned to normal values in 3 to 6 months (15).

Also, by assessing the usefulness of CA 19-9 in patients with pancreatic cancer versus those with benign lesions, the Safi et al. group found in 92% of patients with pancreatic adenocarcinoma a higher than normal level >37 U/ml, for 775 values > 120 U/ml, with a median value of 528 in patients neoplasm. In contrast, they also found values of 18, 14 and 7 U/ml in patients with chronic pancreatitis, acute or concerned with other benign tumors.

In addition, on another group of patients with different forms of neoplasia: colorectal, gastric, esophageal or extra digestive neoplasia, the CA 19-9 levels for most patients were within normal limits. Moreover, in this series, the sensitivity, specificity and accuracy were 92 %, 85% and 82 % respectively (16).

Moreover, Berger et al. have analyzed retrospectively 129 patients who have had determinations of THAT 19-9 before resection with the visa - mapping between the years 1990 and 2002. They have studied not only the correlation between the level of antigen and recurrence or survival and digestive patients with detectable antigen in serum. The level of the fact that a good preoperative neurological 10-9 has been grouped into 4 categories: undetectable, normal <37, increased 37 to 200 and more than increased > 200 U/ml. Also, the results were contained between 0 and 16.300 U/mL. The median overall survival and survival at 5 years were of 19 months and 11 % respectively (10).

Also, survival was similar between non-secretory and those with normal level, and for both groups the survival was statistically significantly higher than of the other 2 groups with values elevated above normal ($p = 0,003$). The only significant predictive factor for survival, after the univariate and multivariate analysis was the presence of tumor adenopathies ($p = 0.015$ and 0.002) and the level of CA 19-9 ($p = 0.003$). In this way, although the group of patients with normal and undetectable values was submitted with advanced disease, the overall survival was superior (10).

Moreover, there are few studies in the literature about CA 19-9 non-secretory patients. It might be foreseeable that these patients would have a worse prognosis because the level of antigen can not be assessed and, therefore, the prediction for the response to treatment, and for the recurrence and survival is not possible. However, in the study we mentioned before, the non-secretory group had the same prognosis as the one with normal values of the antigen during the preoperative stage. The median survival for these 2 groups of patients was similar: 32 and 35 months respectively. Furthermore, these patients had a significantly better survival than those with higher levels of CA 19-9.

In fact, the patients with undetectable level of antigen have a much higher median value of recurrence-free survival than the other groups: 27 vs. 14, 10 and 10 months respectively, despite the fact that it did not present a clear statistical significance. Also, the second positive predictive factor resulted through uni- and multivariate analysis was the presence of tumoral adenopathies, a fact found in other studies as well. Yet it is difficult and early to draw definitive conclusions because the groups of patients are not numerically statistically sufficient. Also it remains unclear why the CA 19-9 non-secretory patients have better prognosis even if the tumor adenopathies are present. For this reason, the aforementioned authors considered that for resected patients in which the CA 19-9 preoperatory level of is undetectable, the aggressive surgery/therapy must and it is worth being performed (10).

FOCUSING ON CYTOKERATINS

In this way, cytokeratins (CK) are epithelial cellular markers useful in determining the tumoral genesis in multiple neoplasms. The cellular structure of mammals includes 3 different types of protein families: actin-containing microfilaments, microtubules containing tubulin and intermediate filaments. The latter include cytokeratins, desmin, vimentin, neurofilaments and glial fibrillar acidic filaments, representing in fact a family of proteins involved in cell differentiation processes (17-19).

Generally speaking, two cytokeratins have been more intensively studied: CK 7 and CK 20, mainly due to their complementary distribution in normal epithelium and malignant tumor tissue.

In this way, CK 7 is expressed in lung, breast, ovary and endometrium, while CK 20 is found in the gastrointestinal epithelium, urothelium and Merkel cells. Also, it is believed that an alteration of the cellular structure that includes the expression of CK 20 may be due to more aggressive tumor development. Also, a variation of the type of expression of CK 20 in neoplasic lesions has predictive value for the recurrence of the disease. Moreover, the expression of cytokeratins and in particular the CK 20 in neoplasic lesions can be an indicator of poor tumor cell differentiation.

Thus, in a study by Wildi et al., the authors describe the over expression of CK 20 on a significant number of specimens with pancreatic cancer, while its prevalence and significance have not been explored (20). Moreover, the expression of cytokeratins, including CK 20, correlated with the degree of cell differentiation. In this way, a possible explanation for the prognostic significance of CK 20 might be that the specific gene is associated with the neoplasic lesion grading as a marker of differentiation, and CK 20 gene expression is correlated with more aggressive tumor biology.

Also, Winnenthal et al. have investigated the possible correlation between the expression of CK 20 in pancreatic cancer and the infaust prognosis of these patients. In this way, they monitored the R0 operated patients for pancreatic tumors and correlated the presence or absence of CK 20 with survival. The cytokeratins are surface cell markers and therefore may be used in the determination of micrometastases in hematopoietic organs. Also, in particular CK 20 was used to detect the dissemination of neoplastic cells using reverse transcription-polymerase chain reaction (RT-PCR) or immunohistochemistry in bone-marrow

cells, venous blood, or lymph nodes in patients with cancer (21).

Moreover, for colorectal and thyroid neoplasm a correlation between CK 20 positive cells from blood and bone marrow and tumoral stage has been described. In this way, because pancreatic neoplasm has high potential for metastasis, the presence of CK 20 cells in blood has been suggested as a possible marker with high sensitivity in determining the micrometastases. Also, tumoral tissue samples from 63 patients with pancreatic cancer were studied for the presence of CK 20 using the RT-PCR. 34 out of the 63 patients have benefited from R0 resection and were monitored for survival. From these 34 patients, 26 (76%) exhibited positive 20 CK cells and 8 (24%) negative CK20. The average period of monitoring for the entire group was 17 months (limits between 4-36 months) while the monitoring period for 'censored' patients was 23 months (between 10-36 months). Also, in the subgroup of R0 resected patients, 3 (38%) of the 8 patients with negative CK 20 neoplasms and 16 (62%) of the 26 patients with positive CK 20 tumors ($p=0.15$) have died due to the recurrence of the disease. The median survival for patients with positive 20 CK was 13 months (limits, 4-36), the median survival in the R0 and negative CK 20 group was 26 months (limits, 13-35; $p = 0.06$).

In addition, the differentiated survival observed in the patients with negative CK 20 neoplasm cannot be attributed to tumoral stage or tumoral grading variations. Also, the CK 20 expressed by most pancreatic ductal adenocarcinomas seems to be associated with poor prognosis in the R0 resected patients. These data suggest that negative CK 20 pancreatic adenocarcinomas represent a subgroup of patients with a more favorable prognosis.

In this way, the CK 20 expression in resected patients for pancreatic cancer may be important as a prognostic marker that can be easily detected and measured on tumoral tissue. Uncertainties remain, however, regarding a possible association of CK 20 expression with tumoral grading, if CK 20 expression is an independent prognostic marker and if the results after adjuvant therapy differ depending on the CK 20 expression (21).

Also, unlike breast cancer and other neoplasms, pancreatic adenocarcinoma is relatively a homogeneous disease with respect to its infaust prognosis and very few histological variants, which is reflected in the uniform chemotherapeutic standard protocols. While cytokeratins 7, 8, 18 and 19 serve as indicators of normal pancreatic ductal epithelium and of neoplastic cells, CK 20 is absent in the normal fetal and adult pancreas but appears in 30%-60% of pancreatic carcinomas. These observations lead to the assumption that there might be a subset of pancreatic neoplasms that could be associated with this marker.

In addition, the Matros et al. group have investigated the relevance of two cytokeratins, CK 7 and CK 20, in pancreatic cancer and tried to find associations with some clinical features. For determining the moment of CK 20 expression during the pancreatic karyokinesis evolution, the aforementioned authors have evaluated the CK 20 in cancer precursory lesions, called pancreatic intraepithelial neoplasia (PanIN). Thus, they reported for the first time that CK 20 is useful in identifying the subsets of pancreatic cancer with distinctive features. In this way, the classification of human neoplasias into subtypes represents a breakthrough in understanding the

biological behavior of the cancer and the response to conventional or new therapies. Moreover, in some cases, these subclassifications are made in connection to a therapeutic agent, such as the use of Trastuzumab in breast cancer with HER2 amplifications and Gefitinib in small cells lung cancer and EGFR mutations (22-24).

Moreover, the authors found that patients with tumors that have reduced CK 20 expression have a significantly higher survival and this correlation persists even after adjusting other variables that can alter the results. Also, none of the patients with tumors exhibiting moderate or high CK 20 expression survived more than 26 months. This difference between clinical results is somewhat surprising because CK 20 was originally used as origin marker for tumors whose starting point was unknown.

Also, the aforementioned authors have found the CK 20 expression in early lesions (PanIN), prior to carcinoma, which implies that this aberrant pathway is most often acquired early in the tumor progression, even before the development of the invasion. In this way, the expression of CK 20 was present on a wide range of PanIN injuries including PanIN I lesions, which supports the progression hypothesis from low to high-grade PanIN to invasive carcinoma.

Thus, the transition from an epithelial differentiation path with CK 20 present seems to appear very early in the progression of neoplastic lesions and maintains during the development of the invasion. Moreover, recent studies concerning intraductal papillary mucinous neoplasm (IPMN) showed a similar divergence in the differentiation and the progression of non-invasive neoplasms. Also, the IPMN intestinal type is more likely to be positive CK 20 and also more likely to be associated with mucinous adenocarcinoma, when the malignancy is present. In addition, another subdomain in which the epithelial differentiation and cytokeratins profile have been studied is the ductal acinar metaplasia process that occurs in chronic pancreatitis (25).

Also, for the studied group, although CK 7 was highly present in the non-neoplastic lobular tissue, the CK 20 presence was not traced in the non-neoplastic pancreatic ducts. In this way, these findings suggest that the transition to CK 20 positivation appears in PanIN early stages and support the hypothesis that pancreatic ductal epithelial neoplasms may progress onto another distinct carcinogenic path.

In the future, with the development of the researches in the field of pancreatic cancer concerning the diagnosis and management of epithelial noninvasive lesions of high risk, further studies will probably also investigate the role of CK 20 expression in predicting neoplasia development.

Also, despite the recent breakthroughs in understanding the genetic impairments/deterioration in pancreatic cancer, little progress has been made in terms of natural aggressiveness and the reduced survival that characterize this disease. Thus, the general trend is to consider the cancer of the pancreas as a single type of disease, but recent research and findings from other neoplasias have resulted in subclassifications very relevant in terms of the treatment algorithm and etiopathogenic ways.

In this way, as mentioned before, the CK 20 expression indicates reduced survival. Therefore, CK 20 can be used as a new prognostic marker in clinical management of pancreatic cancer and may lead to the discovery of other etiopathogenic ways in managing this devastating disease (18).

Also, the group of Roder et al. (26) has proposed the idea that often the pancreas cancer is being substaged and in many patients, at whom the tumor is considered resectable, the disease is actually systemic from the beginning. In this way, by using immunohistochemistry tests, the aforementioned authors have determined neoplastic pancreatic cells disseminated in bone marrow using monoclonal antibodies (mAbs) CK2, KL1, and A45-B/B3 anti-cytokeratins.

Moreover, prior to operation, bone marrow from the antero-superior iliac crest was sampled from 48 patients and compared to bioptic products from 33 healthy subjects. In this way, 14 (48.4%) of the 31 patients with R0 resections and 10 out of 18 (58.8%) with expanded disease exhibited positive CK cells. Still, there was no significant difference between patients regarding the different stages or the presence of lymph nodes metastases. After a median period of postoperatory monitoring of 22.8 months (3 - 48 months), 6 of 15 (40.0%) patients with R0 resection and tumor cells in the bone marrow exhibited distant metastasis and 7 (46.7%) had local recurrence, as compared with none of the 12 free CK-positive cells patients ($p < 0,05$).

Thus, the univariate analysis revealed that the presence of CK-positive cells has predictive value for reduced survival. Therefore determining the tumor cells from bone marrow of patients with pancreas cancer may help identifying those patients with increased risk of early metastasis. Moreover, this is also important in determining the prognosis and the consequences of the neo-/adjuvant therapy in early pancreatic cancer (26).

Additionally, in the context of the present discussion we could also remember the relevance of the I-st class histocompatibility complexes - related to A chain (MICA), as a relevant aspect for the subject studied here. In this way, Weber et al. (27) reviewed the expression of various major I-st class histocompatibility complexes - related to A chain (MICA), as a transmembranary protein or a soluble protein from the serum of 61 patients with pancreatic cancer and 33 healthy subjects using the ELISA test. Also, MICA relates to a receiver of the NKG2D natural killer cells and is increased in some epithelial cancers: gastric, breast, colon, and melanomas.

In this way, the results indicated that serum MICA in patients with pancreatic cancer were significantly higher than in healthy subjects (1107 pg/mL vs 215 pg/mL, $p < 0,01$). They also showed that the serum level of MICA is lower in T1-T3 tumors (n= 15), when compared to 46 metastatic lesions (437 pg/mL vs. 1325 pg/mL, $p < 0.05$). In addition, MICA serum level in patients with unresectable tumors (n= 37) was significantly higher than in the resected patients (n= 24); (1572 pg/mL vs. 390 pg/mL, $p < 0.05$). Moreover, the survival in resected patients (n= 23) was significantly higher than in the unresected patients (n= 34); (17 months vs. 11 months, $p < 0,05$). Therefore the MICA serum level is significantly increased in patients with pancreatic ductal adenocarcinoma and correlates with tumor size and survival, while also its levels are decreasing after resection and can be used as a prognostic marker (27).

BREAST INFECTIONS: DIAGNOSIS WITH ULTRASOUND AND MAMMOGRAPHY (Abstract): **Aim:** Evaluation of ultrasonographic and mammographic pattern, etiology and risk factors of breast infections. **Material and methods:** Our study included a group of 66 female patients aged 16 to 71 years, examined by ultrasound and mammography in several medical imaging services in Iaşi in the interval 2008-2014; ultrasound was performed in all 66 patients and mammography in 22. **Results:** In our study breast infections occurred mostly during breastfeeding and the most frequent causative agent was *Staphylococcus aureus*; ultrasound established the correct diagnosis in 63 cases and detected one or more of the following aspects in case of breast infections: edema of the fatty tissue, hypoechoic areas in the breast tissue, dilated ducts, or fluid collections. Mammography was not necessary in puerperal mastitis and was performed only in women over 40 years old; in most cases we had encountered a focal asymmetric density which had low specificity for the diagnosis of mastitis or breast abscess. **Conclusions:** Our study proved that ultrasound is a valuable method for the diagnosis of mastitis, especially when an abscess is suspected and established a correct diagnosis in most cases; the abscesses appear as inhomogeneous fluid collections, with poorly defined margins, posterior acoustic enhancement, no Doppler signal inside, sometimes associated with enlarged axillary lymph nodes. Mammography was not helpful for the diagnosis. **Keywords**: BREAST INFECTION, ABSCESS, MASTITIS, ULTRASOUND, *STAPHYLOCOCCUS AUREUS*.

Mastitis and breast abscess appear frequently during breastfeeding (puerperal mastitis) (1); the most frequent causative agents of these infections are *Staphylococcus aureus* (which gives rise very quickly to abscess formation) and *Streptococcus pyogenes* (the manifestation being mastitis, the abscess appearing in the advanced stage) (2, 3). The symptoms of breast infections are: fever, breast pain, swelling breast, palpable breast masses inside the breast. Physical examination can suspect a breast infection, but imaging methods are the ones which confirm the diagnosis (4, 5).

Ultrasound is a valuable method for the diagnosis of mastitis, especially when an

abscess is suspected; ultrasonography can localize, measure and follow-up the abscesses during the treatment (6, 7).

Mammography is not recommended in case of puerperal mastitis. Inflammatory changes increase breast density and can impair the visibility of the lesions.

MATERIAL AND METHODS

This retrospective study included a group of 66 female patients aged 16 to 71 years presenting with one or more symptoms of breast infection and examined by ultrasound and/or mammography in several medical services in Iaşi between 2008 and 2014.

Data were obtained by reviewing the ultrasound and mammography reports and images; the results were processed and interpreted by statistical methods (p value, trend).

RESULTS

All 66 patients were examined by ultrasound and in 20 (30.3%) of them mammography was also performed; 22 (33.3%) abscesses and 44 (66.7%) cases of mastitis, including superficial (30 patients-45.4%) and severe mastitis (14 patients-21.3%) were detected.

We diagnosed 32 (48.4%) breast infections occurring during breastfeeding (15 - 22.7% abscesses and 17 - 25.7% cases of mastitis) and 34 (51.6%) breast infections not related to breastfeeding.

Most cases of severe breast infection (15/66 - 22.7%) occurred during breastfeeding, 5 (7.5%) patients had diabetes mellitus, 2 (3%) of them had no apparent risk factors; 27 (40.9%) women who had superficial mastitis (ultrasound findings: fatty tissue edema and skin thickening) did not have any important risk factors (tab. I).

TABLE I

Risk factors of breast infections

Risk factors	Breastfeeding		Diabetes		No risk factors	
	Abscess	Mastitis	Abscess	Mastitis	Abscess	Mastitis
No. of patients	15	17	5	0	2	27
% of patients	22.7	25.7	7.5	0	3	40.9

In the vast majority of cases breast infections were located on one side: 30 (45.4%) in the left and 35 (53.1%) in the right breast; only one patient (1.5%) had bilateral mastitis.

Breast ultrasound established a correct diagnosis in 63 (95.4%) cases; inflammatory carcinoma was considered in the differential diagnosis in 3 (4.5%) cases.

Mammography was never necessary in puerperal mastitis and was recommended only in women aged over 45-50 years to complete the evaluation of both breasts.

Ultrasonography showed the following:

- in all the cases of superficial mastitis (30 patients-45.4%): fatty tissue edema and thick skin, which correlated with the symptoms were sufficient for the diagnosis; all these patients were treated with antibiotics no case of abscess formation being recorded;

- in case of severe mastitis (fig. 1), one or more of the following: edema of the fatty tissue (37 patients - 56 %), hypoechoic areas in the breast tissue (35 - 53%), dilated retroareolar ducts (34-51.5%), fluid collections (22-33.3%), enlarged axillary nodes (20-30.3%), skin thickness more the 2 mm (19 - 28.7 %), increased vascularisation of the breast tissue (18-27.7 %).

Twenty-two (33.3%) abscesses were detected by ultrasound, which most of the time had a typical pattern: round or oval hypoechoic fluid collections with poorly defined margins, inhomogeneous, with posterior acoustic enhancement, no Doppler signal inside; a fluid-fluid level and internal echoes were identified in one case each; the abscesses were associated with appearances of mastitis in 12 (18.8 %) patients and/or enlarged axillary lymph nodes (12 patients-18.8 %) (fig. 2 a, b).

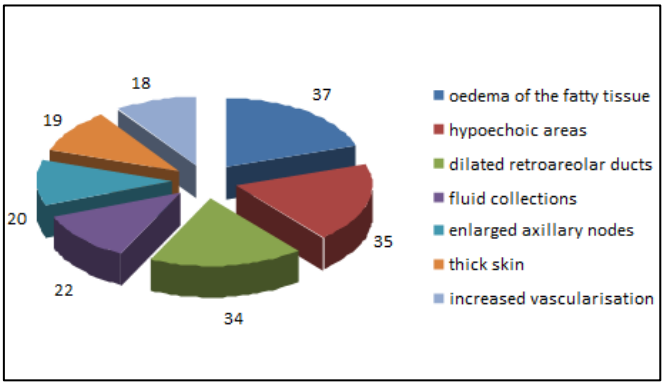

Fig. 1. Ultrasonographic pattern of breast infections

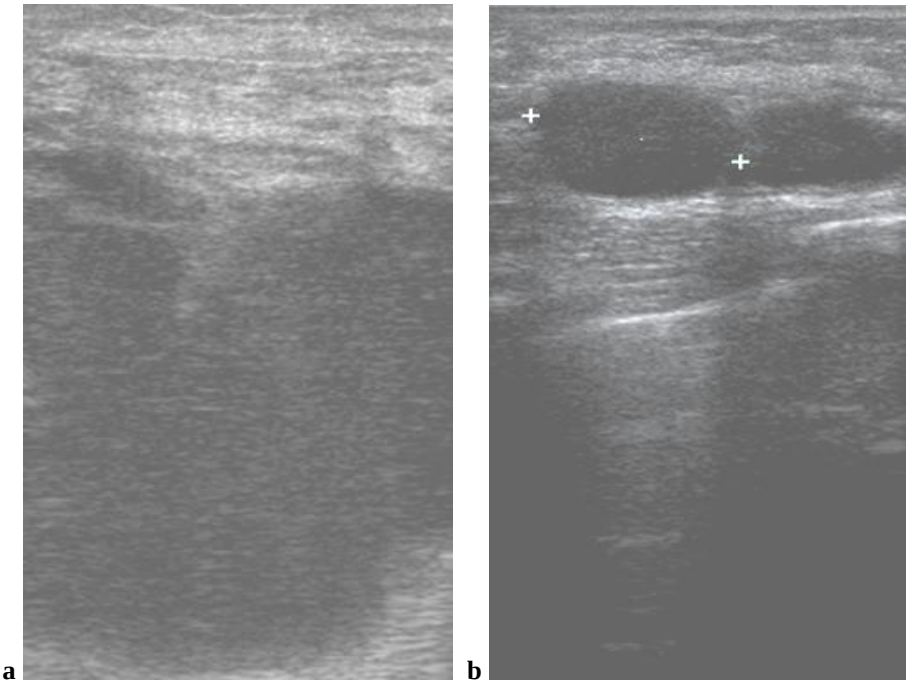

a **b**

Fig. 2 a, b. Breast and axilla ultrasound, B mode: Breast abscess (a), enlarged axillary nodes (b)

Mammography was performed in 22 cases and the findings were: normal in 3

(13.6%) cases, breast edema (increased density of the breast, with effacement of the normal structures) -2 (9%) cases and thick skin (1 case - 4.5%); only in 1 patient (4.5%) with breast abscess mammography discovered a high intensity, homogeneous, oval mass, with poorly defined, irregular margins; in our study in most cases of breast infections (15 cases - 68.1%) mammography showed a focal asymmetric density (fig. 3, 4).

The treatment of breast infections was antibiotic therapy in 48 (72.8%) cases (the patients with mastitis and 4 of the patients with abscesses), antibiotic therapy, incision and drainage in 17 (25.7%) patients with breast abscesses; in one (1.5%) patient after surgery ultrasound guided fine needle aspiration of the remaining collection was also performed.

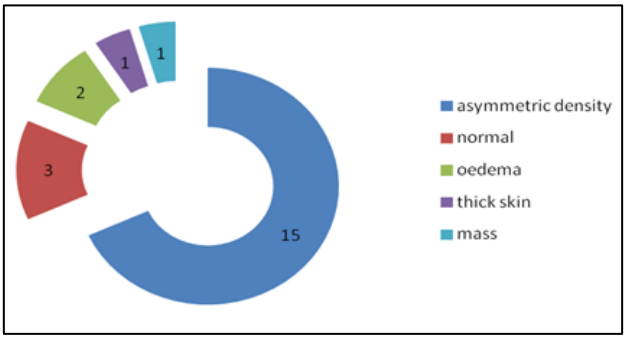

Fig. 3. Mammographic pattern of breast infections

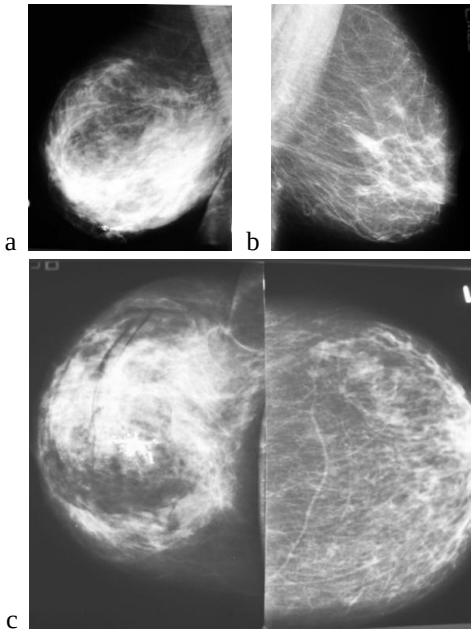

Fig. 4 a, b, c. Bilateral mammography, oblique (a, b) and cranio-caudal (c) views: asymmetric density in the inferior quadrants of the right breast

The causative organisms were studied in 39 (59%) breast infections: 22 (56.4%) abscess cultures and 17 (43.6%) breast milk cultures; the results of the cultures were as follows (tab. II): *Staphylococcus aureus* (33 cultures-84.7%), *Streptococcus pyogenes* (5 cultures-12.8%), *Bacteroides spp.* (1 culture - 2.5%).

TABLE II
The causative organisms of breast infections

Causative organism	No. of patients	% patients
Staphylococcus aureus	33	84.7
Streptococcus pyogenes	5	12.8
Bacteroides spp.	1	2.5

DISCUSSION

In our study, breast infections occurred during breastfeeding (32 - 48.4% patients) and related to diabetes mellitus (5 - 7.5% patients), but 27 (40.9%) women with superficial mastitis and 2 (3%) with breast abscesses had no apparent risk factors for breast infections; less than 50% of breast infections were related to breastfeeding, but this was the most common risk factor in our study. Most infections were caused by *Staphylococcus aureus* (33 infections-84.6 %), accordingly to the literature (8, 9).

Ultrasonography showed edema of the fatty tissue and thick skin in all cases of superficial mastitis, which correlated with the symptoms were sufficient for the diagnosis (10, 11).

In case of an extended breast infection one or more of the following signs of mastitis was present: hypoechoic areas (35 - 53% cases) with increased vascularization (18-27.7% cases) in the breast tissue, dilated retroareolar ducts (34-51.5%), axillary lymphadenopaties (20-30.3%), which along with pain and swelling breast were diagnostic in all cases.

We found at ultrasound 22 (33.3%) abscess, which appeared as hypoechoic collections, with a diameter of 3 to 7 cm; 20 (30.3%) collections were inhomogeneous, with internal echoes and poorly defined, irregular margins; in one case (1.5%) the hypoechoic image was homogeneous and in 1 case (1.5%) had a fluid-fluid level; the lesions were associated with aspects of mastitis in 12 (18.18%) cases and enlarged axillary lymph nodes were present in 12 (18.18%) patients. Only in 3(4.5%) patients the hypoechoic masses appeared to be solid and an inflammatory tumor was suspected (12).

Mammography was performed only in 20 (30.3%) cases and the images were not helpful for the diagnosis; in most cases (15-22.7%) we found a focal asymmetric density with poorly defined, irregular margins which had to be further studied by ultrasound.

CONCLUSIONS

Our study proved that ultrasound is a valuable method for the diagnosis of mastitis, especially when an abscess is suspected and makes a correct diagnosis in most cases. The abscesses appeared as inhomogeneous fluid collections with poorly defined margins, posterior acoustic enhancement, no Doppler signal inside, associated with enlarged axillary lymph nodes. Mammog-

raphy was not helpful for the diagnosis; in most cases we found a focal asymmetric density which has low specificity for the diagnosis of mastitis and breast abscess.

EPIDEMIOLOGICAL EVALUATION OF VIDEO-ASSISTED THORACOSCOPY OUTCOMES IN NEOPLASTIC PLEURISY (Abstract). **Aim:** Clinical-epidemiological investigations for further assessing the importance of video-assisted thoracoscopy in the treatment y of patients with neoplastic pleurisy. **Materials and methods**: The researches included a group of 72 patients (31.9% men and 68.1% women aged 31-81 years, mean age ± 60 years) with neoplastic pleurisy who underwent pleural symphysis by video-assisted thoracoscopic talcage.. For statistical-mathematical processing and interpretation the Pearson correlation index with the level of significance at $p = 0.05$ and highly significant at $p < 0.005$ was used. **Results:** Neoplastic pleurisy prevalently affected the age groups 51-80 years (84.9%). Dyspnea was present in all cases, and patient history at the time of admission revealed 14 conditions, of which 25% were lung cancers. Macroscopically nodular and vegetative tumors were found in 66.7% of cases. An amount of 1000 - 2000 ml of pleural fluid was found in 44.5% of the cases and a serocitrin appearance in 50%. In 23.6% of the cases cytology results were positive for malignancy and in 13.8% suspicious. In 65.2% of the cases the pleural fluid was exudative and anatomopathology was suggestive of adenocarcinoma in 34.7% of the cases and breast cancer in 18%. The prevalence of recurrences varied from 1 month to more than 7 months, with 36.4% for 1-2 months. **Conclusions**: The obtained additional data support the important role of pleural symphysis by video-assisted thoracoscopic talcage in the patients with neoplastic pleurisy. **Keywords:** PLEURAL NEOPLASIA: VIDEO-ASSISTED THORACOSCOPY, HISTORY, RECURRENCE, TALCAGE, PLEURAL SYMPHYSIS

In cancer patients, pleural fluid can initially accumulate asymptomatically, possibly associated with that present in the pericardium and peritoneum. (1, 2, 3). In symptomatic pleurisy pleural fluid accumulation occurs during anticancer therapy without requiring local treatment, but in patients in which the neoplasm is not responding to systemic therapy it requires local treatment.

Tumor-induced pleural fluid may or may not contain malignant cells. In 75% of the lung cancer, breast cancer or lymphoma cases the pleural fluid is present.

In symptomatic pleurisy thoracentesis is the first-line procedure and when the fluid returns the drainage tube is necessary for up to two weeks by aspirating 100 ml in 24 hours. Antibiotics and anticancer drugs are introduced according to the established schedule through the drainage tube

(4,5,6,7,8).

Neoplastic pleurisy tends to recur and cause severe inspiratory distress and treatment-refractory state. These symptoms significantly affected the quality of life of patients (8,10).

Therefore, the palliative treatment of neoplastic pleurisy is required in all situations and is consists in the obliteration of the pleural space by video-assisted thoracoscopic talcage (1,12).

MATERIAL AND METHODS

The study included a group of 72 patients (31.9% men and 68.1% women, aged 31-81 years, mean age ± 60 years) with neoplastic pleurisy who underwent video-assisted thoracoscopy completed by talcage.

Information was gathered based on an epidemiological case sheet and data from patients' medical records according to the ethical and legal guidelines.

For statistical-mathematical processing and interpretation the Pearson correlation index with the level of significance at $p = 0.05$ and highly significant at $p < 0.005$ was used.

RESULTS

1. Age-group distribution showed that metastatic neoplastic pleurisy prevalently affected the age groups 51-80 years (84.9% of the total) compared to 12.4% in age-groups 21-50 years, the difference being highly significant ($p < 0.005$) (fig. 1).

2. Admission symptoms. Dyspnea was present in all 72 patients, followed by dry cough, chest pain, chest twinge, productive cough, and fatigue state (fig. 2).

3. Prevalence of prior history recorded on admission included 14 entities with a frequency ranging from 25% for lung cancer to 2.8%, and 22 pathological manifestations recoded in 1 case each (1.4%).

A highly significant prevalence ($p < 0.005$) was found for the first 4 entities: lung cancer, breast cancer, hypertension, and chemotherapy which accounted for 70.8% of the total of 72 patients with metastatic neoplastic pleurisy (tab. I).

One case each (1.4%) of operated brain metastasis, pleurisy, liver metastases, bone metastases, cutaneous squamous cell carcinoma, heart disease, esophageal varices, thrombophlebitis, operated ovarian cyst, chronic heart failure, obstructive arteriopathy, type II diabetes mellitus, lung metastases, operated gastric cancer, leukemia, Hodgkin's lymphoma, mesothelioma, liver cirrhosis, thyroid carcinoma, operated melanoma, non-Hodgkin lymphoma, AIDS were also recorded.

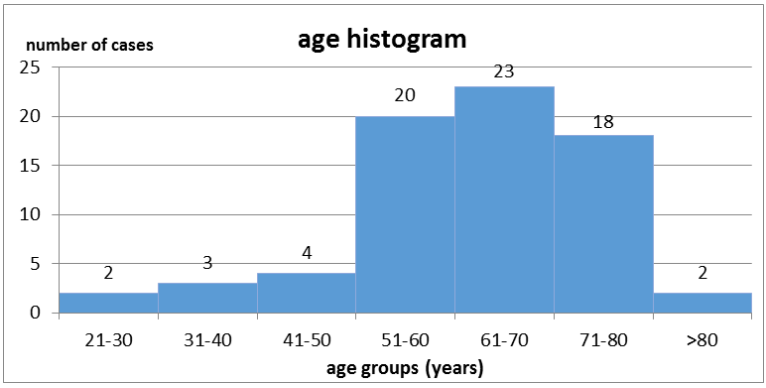

Fig. 1 Age-group distribution of the 72 patients with neoplastic pleurisy

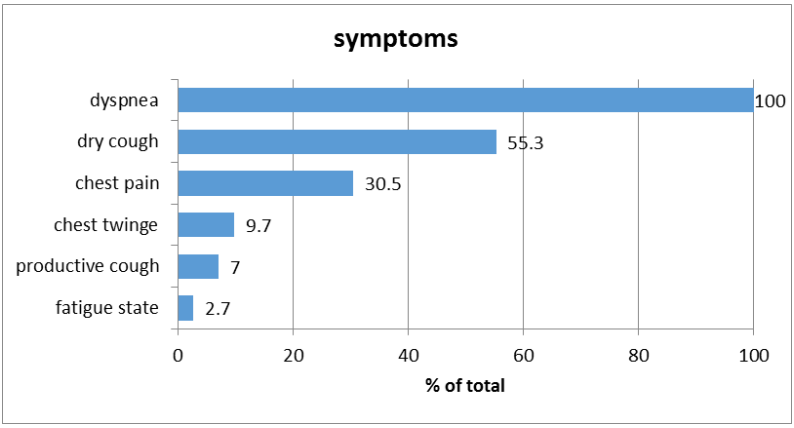

Fig. 2 Admission symptoms in the 72 patients with neoplastic pleurisy

TABLE I

Prevalence of prior history recorded on admission in the 72 patients with metastatic neoplastic pleurisy

Prior history	Nr.	%	Prior history	Nr.	%
Lung cancer	18	25.0	Stroke	2	2.8
Operated breast cancer	16	22.2	Pleural metastases	2	2.8
Arterial hypertension	9	12.5	Radiotherapy	2	2.8
Chemotherapy	8	11.1	Tuberculosis	2	2.8
Operated uterine cancer	5	7.0	Malignant melanom	2	2.8
Operated uterine fibroma	4	5.5	Ischemic cardiopathy	2	2.8
Operated ovarian cancer	3	4.1	Prostate adenoma	2	2.8

4. Detection of metastatic pleural lesions. Macroscopic examination revealed the presence of nodules, vegetative tumors, absence of tumoral features and presence of whitish placards. Nodules and vegetative tumors were present in 66.7% of the cases, the difference between them and the other two remaining findings being highly statistical significant ($p < 0.005$) (Fig. 3).

5. Amount and macroscopic appearance of pleural fluid showed that 1000-2000 ml of pleural fluid was found in 44.5% of cases and a serocitrin appearance in 50.0% (Tab. II).

6. Pleural fluid cytology was positive for malignancy in 23% of cases and suspicious in 13.8%. In a total of 37.4% of the cases cytology suggested a diagnosis of neoplastic pleurisy (fig. 4).

7. Pleural fluid biochemistry. The pleural fluid from neoplastic patients was overwhelmingly of exudative type (65.2%) with a highly significant difference ($p<0.005$) compared to the transudative type (13.8%) (tab. III).

8. The prevalence values of anatomopathological findings pleaded for the diagnosis of malignancy in 65.3% of cases (tab. IV).

9. Frequency of recurrence according

to the interval (months) from surgery showed that recurrences were recorded in 11 (15.3%) of the 72 study cases as follows: after 1 - 2 months = 36.4%; after 4-5 months = 27.2%; ≥ 7 months= 34.4% (tab. V). The 11 (15.3%) cases with recurrence of neoplastic pleurisy were almost equally dispersed in the three time intervals. 1-2 to ≥ 7 months.

10. Length of hospital stays (days) for patients with metastatic pleurisy reflect, at least in part, the costs of care. A hospital stay of 5-10 days was recorded in 73.5% of the 72 study patients (tab. VI).

19 -20	2	2.8
Total	**72**	**100.0**

DISCUSSION

In agreement with our findings, other authors (12,13) have highlighted the importance of pleural symphysis by video-assisted thoracoscopic talcage in patients with neoplastic pleurisy (5). Thus, Horvat (11) states that the main indications of video-assisted thoracoscopy are: evaluation of malignant pleural fluid collection, hilar and mediastinal lymphadenopathy, and performing lung biopsies.

If by the previously used procedures in over 40% of the patients with malignant pleurisy the cytological and histopathological results were inconclusive, the diagnostic accuracy of video-assisted thoracoscopy is about 90%. Procedures performed using this technique include pleural and lung biopsy, lysis of adhesions, partial pleural decortication, pleurectomy, pleurodesis and diagnosis of entire pleural cavity.

Homer (12) points out that although used since 1930 - 1940 thoracoscopy is back in current use, with the advent of video system, video-assisted thoracoscopy being a procedure that can be performed without difficulty and risks at an acceptable cost.

Video-assisted thoracoscopy can be performed under local (10 to 15 ml 1% lidocaine) or general anesthesia, and is particularly useful in the diagnosis of pleural disease or for obliterating the pleural space by video-assisted thoracoscopy with talcage.

Other authors (12,13) also insists on the fact that by identifying malignant cells pleural fluid cytology makes an accurate diagnosis of neoplastic pleurisy. More sensitivity may be added to this exam by using monoclonal antibodies, molecular biology techniques and cytogenetics.

CONCLUSIONS

Our clinical-epidemiological research of a representative group of patients provides additional evidence on the importance of video-assisted thoracoscopy in the diagnosis and therapy of neoplastic pleurisy and a better quality of life of these patients.

Of the 72 study patients with metastatic pleurisy included in the study in 56 (77.7%) video-assisted thoracoscopy was followed by aseptic talcage that resulted in stopping the production of pleural fluid.

NEWS

IS ROBOTIC PARATHYROIDECTOMY A FEASIBLE AND SAFE ALTERNATIVE TO TARGETED OPEN PARATHYROIDECTOMY FOR THE TREATMENT OF PRIMARY HYPERPARATHYROIDISM?

A best evidence topic was written according to a structured protocol. The question addressed was whether robotic parathyroidectomy (RP) is a feasible and safe alternative to targeted open parathyroidectomy for the treatment of primary hyperparathyroidism (pHPT). A total of 36 papers were identified using the reported searches of which 5 represented the best evidence to answer the clinical question. The authors, date, journal, study type, population, main outcome measures and results are tabulated. Targeted parathyroidectomy constitutes the co-gold-standard procedure for pHPT with results equivalent to bilateral cervical exploration. This has led to the proliferation of minimally invasive parathyroidectomy (MIP) techniques for pre-operatively localised adenomas. None has been shown to be overwhelmingly superior. RP constitutes the most recent addition. RP overcomes the limitations of conventional endoscopic surgery and simultaneously avoids a neck scar by concealing it in the axilla or infraclavicular area. The evidence from the present review shows that RP is feasible and leads to a superior cosmetic result compared to targeted open parathyroidectomy (TOP) with an equivalent safety profile. As with every surgical technique, appropriate patient selection is crucial. Long-term data are currently awaited on RP especially in view of its high cost and long operative time compared to TOP and other MIP techniques. Hence, RP offers a viable but costly alternative to other forms of MIP in patients where even the smallest and most cosmetic neck scar is not an option (Garas G, Holsinger FC, Grant DG, Athanasiou T, Arora A, Tolley N. Is robotic parathyroidectomy a feasible and safe alternative to targeted open parathyroidectomy for the treatment of primary hyperparathyroidism? *Int J Surg* 2015 Jan 29;15C:55-60. doi: 10.1016/j.ijsu. 2015.01.019. THROMBOTIC EVENTS IN PATIENTS WITH HEPATITIS C VIRUS LIVER CIRRHOSIS TREATED WITH DIRECT ACTING ANTIVIRALS AND SUSTAINED VIROLOGICAL RESPONSE (Abstract): The advent of direct-acting antivirals (DAAs) is a major breakthrough in hepatology representing the therapeutical standard of care in patients with chronic hepatitis C virus infection over the past few years. Despite high rates of sustained virological response (SVR), DAAs therapy doesn't eliminate the risk of thrombotic events. **Aim**: We aimed to assess the incidence and risk factors of thrombotic events in patients with SVR treated with DAAs. **Material and methods:** We retrospectively analyzed a cohort of patients with HCV-related liver cirrhosis treated with paritaprevir/ritonavir, ombitasvir and dasabuvir (PrOD) ± ribavirin and ledipasvir/sofosbuvir (LED/SOF) ± ribavirin for 12/24 weeks, in a tertiary gastroenterology referral center from North-Eastern Romania, between January 1st 2016 and January 1st 2018. All patients with presumption of thrombosis were evaluated by vascular Doppler, abdominal ultrasound and confirmed by CT scan. **Results:** The study included 321 HCV-infected cirrhotic patients treated with PrOD or LED/SOF, with documented SVR, mean age 59,7 ± 8,5 years, predominantly female (59%). Of the total number, 307 (95.63%) received PrOD and 14 (4.36%) patients were treated with LED/SOF. Mean period from SVR and the occurrence of thrombotic events was 250±123 days. Thrombotic complications were reported in **14** (4.36%) patients: 4 (28.57%) with deep vein thrombosis, 4 (28.57%) with portal vein thrombosis (PVT), 6 (42.85%) with malignant PVT. All patients had associated cardiovascular (8- 57.14%) and metabolic comorbidities (6- 42.85%). The main clinical manifestations at diagnosis were: swelling, edema, erythema and lower limb pain in 4 patients, upper digestive hemorrhage in 2 patients, ascitic decompensation in 4 patient and 4 patients were asymptomatic. Biologically there was no significant change in prothrombin serum levels (baseline values in patients treated with PrOD was 11.67 ± 0.91 versus 11.70 ± 0.83 at SVR, p=0.993, respectively 11.5 ± 0.84 sec at baseline versus 11.4 ± 0.68 at SVR, p=0.715 in patients treated with LED/SOF+RBV) and platelet count (126 000 (101 500-162 000) vs. 131 000 (101 000-165 000), p= 0.818 in patients treated with PrOD, respectively 94857.14 ± 32 vs. 92428.57 ± 35, p= 0.853, in patients treated with LED/SOF+RBV). **Conclusions**: We conclude that thrombotic events in patients with HCV-related liver cirrhosis treated with DAAs are not influenced by the variations of coagulation parameters, rather correspond to the hypercoagulability status of the cirrhotic patient. **Keywords**: DIRECT ANTIVIRALS, SUSTAINED VIROLOGIC RESPONSE, THROMBOSIS.

Hepatitis C virus infection (HCV) described by Choo in 1989, represents an important public health problem and according to WHO, there are about 71 million people worldwide with HCV chronic infection (1).

HCV- related liver cirrhosis is a pathology commonly encountered in the current practice, which is associated with increased rates of morbidity and mortality. The complications of liver cirrhosis frequently occur in the evolution of the disease, with a negative impact on the prognosis of patients.

The last years have brought a change regarding the condition of hemostasis in cirrhotic patients. The concept according to which the cirrhotic patient is predisposed to hemorrhagic complications and protected against thrombotic events has been redefined in recent years (2). Studies in this field have shown an equilibrium between the procoagulant and the anticoagulant factors which cause the cirrhotic patient to be in the middle of a very sensitive balance, that can lean the plates towards bleeding or thrombosis (3,4).

The changes that determine a hypercoagulability status in liver cirrhosis are represented by a decrease synthesis of the anticoagulant factors: protein C, protein S and antithrombin III and an increase of von Willebrand factor and VIII factor (5), which may explain the relatively high incidence of thrombotic events among these patients, the most commonly reported being portal thrombosis (PVT) and deep vein thrombosis (DVT) (6).

Direct-acting antivirals (DAAs) have radically changed the management of chronic HCV infection over the past 3 years, with a safety profile and high rates of SVR (>95%). The DAAs mechanism of action directly targets viral protease, polymerase and nonstructural proteins, thus allowing for a high rate of viral clearance without significant side effects (7).

Recent studies have shown the positive impact on liver function, as measured by the CHILD-PUGH and MELD score improvement, as well as the decompensation rate after obtaining sustained virological response with the new oral direct-acting antivirals, but there are no conclusive data regarding the effect on clotting disorders from liver cirrhosis (8,9). In our study, we aimed to assess the incidence and risk factors of thrombotic events in patients with SVR treated with DAAs.

MATERIAL AND METHODS

This is a retrospective study in which we included patients with HCV-related liver cirrhosis which fulfilled the criteria for antiviral therapy, in a tertiary gastroenterology referral center from North-Eastern Romania, between January 1st 2016 and January 1st 2018. The inclusion and exclusion criteria were according to our National Protocol. The regimens used were: Paritaprevir/Ritonavir, Ombitasvir and Dasabuvir (PrOD) ± Ribavirin in patients with HCV-related compensated liver cirrhosis (LC) and Ledipasvir/Sofosbuvir (LED/SOF) + Ribavirin (RBV) for 12 weeks, in patients with decompensated LC. Diagnosis of cirrhosis was established based on clinical features, blood tests and imaging methods.

The study protocol was approved by the Ethical Research Committee of "Grigore T. Popa" University of Medicine and Pharmacy Iasi and by the Ethical Committee of the "Sf. Spiridon" County Clinical Emergency Hospital. All patients were required to sign an informed consent.

All patients with presumption of thrombosis were evaluated by imaging methods and blood samples. Blood tests were performed at baseline, end of treatment (EOT) and 12/24 weeks after EOT (sustained virological response- SVR12). The imaging tests were: vascular Doppler (SONOTRAX 4, vein ultrasound 4 MHz), abdominal ultrasound (Philips HD 11xe ultrasound system) and computer tomography (Siemens Somatom Emotion 16). Echographically, thrombosis was defined as the presence of a hyperechogenic material within the vascular lumen.

Data collected was statistically analyzed using SPSS 20.0 (Chicago, IL, SUA). All tests were two-tailed with p-value <0.05 was considered statistically significant. The quantitative variables were compared using the t-Student test, and the qualitative parameters were evaluated by the chi-square test.

RESULTS

The study included 321 HCV-infected cirrhotic patients treated with PrOD or LED/SOF, between January 1st, 2016 and January 1st 2018, with documented SVR, mean age 59,7 ± 8,5 years, predominantly female (59%). Of the total number, 307 (95.63%) received PrOD and 14 (4.36%) patients were treated with LED/SOF+RBV. Child-Pugh score at baseline was 7.64 ± 1 in the LED/SOF group versus 5.06 ±0.24 points. Main demographic characteristics are presented in table I.

TABLE I

Demographic characteristics at baseline

Demographic characteristics at baseline	All (n=321)
Females, n(%)	190 (59%)
Age (mean ± SD)	59,7 ± 8,5
Treatment Regimen	
PrOD, n(%)	307 (95.63%)
LED/SOF+RBV, n(%)	14 (4.37%)
CHILD-PUGH Score	
PrOD (mean ± SD)	5.06 ± 0.24
LED/SOF+RBV(mean ± SD)	7.64 ± 1

All patients had SVR documented by undetectable HCV-RNA. In patients treated with PrOD, GGT, AST and ALT had significant decreased values at SVR12 compared to baseline (p<0.001). Also, in the LED/SOF+RBV group, transaminases levels had an improving trend (p<0.001) (tab. 2 and 3).

Mean period from SVR and the occurrence of thrombotic events was 250±123 days. Thrombotic complications were reported in 14 (4.36%) patients: 4 (28.57%) with deep vein thrombosis (DVT), 4 (28.57%) with portal vein thrombosis (PVT), 6 (42.85%) with malignant PVT (fig. 1). All patients had associated cardiovascular (8- 57.14%) and metabolic comorbidities (6- 42.85%). The main clinical manifestations at diagnosis were: swelling, edema, erythema and lower limb pain in 4 patients, upper digestive hemorrhage in 2 patients, ascitic decompensation in 4 patients and 4 patients were asymptomatic (fig. 2).

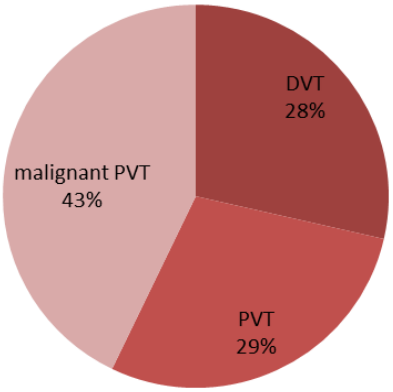

Fig. 1. Thrombotic events after SVR12 PVT= portal vein thrombosis, DVT= deep vein thrombosis, malignant PVT= malignant portal thrombosis

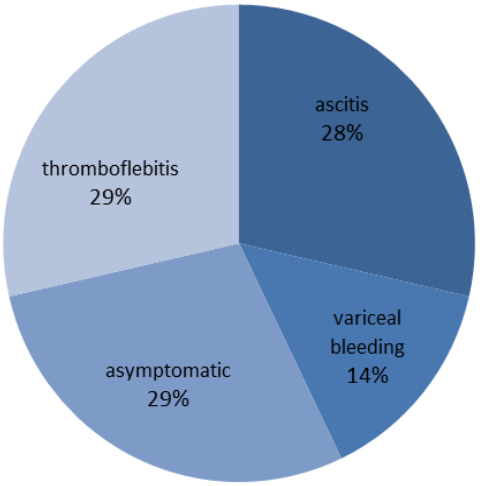

Fig. 2. Clinical manifestations at diagnosis

There was no significant change in prothrombin serum levels in both groups: baseline values in patients treated with PrOD was 11.67 ± 0.91 versus 11.70 ± 0.83 at SVR, p=0.993, respectively 11.5 ± 0.84 sec at baseline versus 11.4 ± 0.68 at SVR, p=0.715 in patients treated with LED/SOF+RBV (fig. 3).

Platelet count had no significant changes at baseline versus SVR in both groups (126 000 (101 500-162 000) vs. 131 000 (101 000-165 000), p= 0.818 in patients treated with PrOD, respectively 94857.14 ± 32 vs. 92428.57 ± 35, p= 0.853, in patients treated with LED/SOF+RBV) (fig. 4).

DISCUSSION

The available data from the last few years showed that there is an imbalance concerning the hemostasis status in cirrhotic patients which are nowadays considered to be predisposed to thrombotic events; recent studies have demonstrated a disequilibrium between pro- and anticoagulants factors in cirrhotic patients.

The last few years brought an important change in the therapeutic management of chronic HCV infection. The advent of DAAs represents a breakthrough in hepatology, with a safe profile and high rates of SVR (>97%) (10). Available data shows an improvement in liver function after achieving SVR with DAAs in cirrhotic patients assessed by decreased MELD and CHILD-PUGH scores after 12 weeks from end of treatment EOT (8,9). There are very few studies regarding the coagulation status of cirrhotic patients with SVR treated with DAAs. In our study we aimed to assess the incidence and risk factors of thrombotic events in patients with SVR treated with DAAs.

Most biochemical parameters showed an improvement on SVR12 compared to baseline. Transaminases and GGT had significantly decreased values in both groups of patients, revealing the disappearance of liver injury due to the viral clearance. Also, we observed a decreasing trend for MELD score, showing an improvement in global liver function.

There was a slight improvement of platelet count after SVR in patients treated with PrOD, but not significantly statistic. We didn't find any improvement in platelet count at SVR compared to baseline in patients treated with LED/SOF+RBV, but on the contrary we identified a slight decrease in platelets that can be explained by splenic sequestration and exaggerated destruction, representing a characteristic status in patients with advanced liver disease. Studies that used radiolabeled platelets have shown a low survival to which is added the low level of thrombopoietin, determined by a decreased synthesis in liver cirrhosis (11). Tripodi et al. did not found an appreciable increase in platelet count in their study lot, incriminating the short period of follow-up and the fact that viral eradication and im-

provement of liver function does not change the splenic pool (12). None of the currently used coagulation parameters in cirrhotic patients (PT, INR) had a notifiable statistic change. This finding confirms the idea that the procoagulant status in cirrhotic patients cannot be reflected only by these laboratory parameters.

Our study showed an incidence of 4.36% of thrombotic events in patients with HCV related liver cirrhosis treated with DAAs.

According to recent studies, the incidence of DVT in cirrhotic patients ranges from 0.5% to 8%, depending on the patient's comorbidities (13). We found in our cohort an incidence rate of 1.24% patients with DVT. All patients which developed DVT associated chronic venous insufficiency. None of these patients had previously been treated for prophylactic purposes with anticoagulants or mechanic methods.

PVT represents the most frequent thrombotic event in cirrhotic patients, the most commonly reported etiology being the HCV infection (14). In our study the incidence of non-malignant PVT was 1.24%, like the findings of Luca et al. which showed an incidence of 0.5%-26% in a cohort of cirrhotic patients (15).

Risk factors that were correlated with PVT were the presence of decompensated liver cirrhosis, ascites and age >50 years. If the first two risk factors are the expression of the severity of the liver disease, age above 50 years associates a cumulus of factors such as the presence of comorbidities and the increasing severity grade of the liver disease.

In our study, the incidence of malignant PVT associated with hepatocellular carcinoma occurred in 43% of patients with thrombotic events, these data being consistent with the literature (16, 17).

CONCLUSIONS

Thrombotic events in patients with HCV-related liver cirrhosis treated with DAAs are not influenced by the variations of coagulation parameters, rather correspond to the hypercoagulability status of the cirrhotic patient. The incidence of thrombotic events in cirrhotic was similar to that reported in specialty literature, remaining to be further demonstrated if the mechanism of DAAs can influence the development of thrombotic events in this type of patients.

NEWS

CDH17 IS A MORE SENSITIVE MARKER FOR DIGESTIVE ADENOCARCINOMA

CDH17 or liver-intestine cadherin, is a cell-adhesion molecule specific to intestinal epithelium, regulated by CDX2 and is involved in the invasion and metastasis process of tumors. A standard panel of CK 7, CK 20, and CDX2 antibodies is usually used in detection of adenocarcinomas of digestive tract. A study compared the usefulness of CDH17 as an immunohistochemical intestinal marker, by evaluating it's sensitivity and specificity in contrast with CK 20 and CDX2. The assessment was done by using immunohistochemistry on formalin-fixed, paraffin-embedded tissue microarrays (TMAs) including normal (n=26) and tumoral tissue (n=884) of colon, stomach and esophagus. CDH17 proved to be a more sensitive and specific marker then CK 20 and CDX2 in diagnose of primary tumors by up to 10% and in metastasis by up to 40%. (Altree-Tacha D, Tyrrell J, Haas T. CDH17 is a more sensitive marker for gastric adenocarcinoma than CK20 and CDX2. *Arch Pathol Lab Med* 2017; 141(1): 144-150).

JOD-BASEDOW EFFECT DUE TO PROLONGED USE OF LUGOL SOLUTION-CASE REPORT (Abstract): Graves' disease is the most common form of hyperthyroidism, accounting for 60-80% of all cases of thyrotoxicosis. If left untreated, it may lead to severe thyrotoxicosis with cardiovascular, ocular, psychiatric complication, and in extreme cases thyrotoxic crisis with a high mortality rate. We present the case of a 50-years-old woman diagnosed in another service with Graves' disease and treated for many years with antithyroid drugs (ATDs), admitted to our service for a relapse due to treatment discontinuation. The surgical treatment was planned and the preoperative preparation with Lugol solution was initiated. Due to a misunderstanding, the administration of iodine solution was extended for a period of about 30 days, thus generating the so-called Jod-Basedow effect, with the exacerbation of the manifestations of thyrotoxicosis and risk of thyroid storm. The patient received treatment with high ATDs doses, glucocorticoids, and beta-blockers, resulting in the progressive improvement of symptoms. She was discharged from hospital and given the risk of thyrotoxic crisis the surgery was postponed. After a month, the patient underwent thyroidectomy without preoperative preparation with iodine solution. The operative and postoperative courses were uneventful. **Keywords:** GRAVES' DISEASE, SURGICAL TREATMENT, LUGOL SOLUTION, THYROTOXIC CRISIS

Graves' disease is the most common form of hyperthyroidism, accounting for 60-80% of all cases of thyrotoxicosis. Its prevalence is estimated to be about 0.6% of population, with a female-to-male ratio of 7:8/1. The disease mainly affects young women, aged 30-60 years (1, 2).

It is an autoimmune disorder due to thyroid receptor autoantibodies (TRAb), also named thyroid-stimulated immunoglobulins (TSI), which stimulate growth of the thyroid gland and overproduction of thyroid hormones. The main clinical manifestations are hyperthyroidism, diffuse goiter, ocular signs, and more rarely dermopathy and acropachy (3). If left untreated it may lead to severe thyrotoxicosis with cardiovascular, ocular, psychiatric complication, and in extreme cases thyrotoxic crisis, with a high mortality rate of about 20% even in our days (4).

The optimal therapy for Graves' disease is still a subject of debate. The main treatment options are represented by antithyroid drugs (ATDs) and ablation therapy: radioactive iodine (RAI) or surgery (5). The used ATDs are methimazole, carbimazole, and propylthiouracil. They are acting by blocking thyroid hormone synthesis and may also control hyperthyroidism by immune suppression (6). A major disadvantage of ATDs treatment, which has traditionally been the first-line treatment in Europe, is the high risk of relapse after discontinuation (50-80% of patients) (5, 7). Surgery is an alternative therapeutic option for Graves' disease in many circumstances. Total thyroidectomy has negligible recurrence rates and high cure rates (8, 9, 10). Preoperative preparation with iodine is used by most surgeons in order to prevent thyrotoxic crisis and complications during thyroidectomy (11, 12).

CASE REPORT

We present the case of a 50-years-old woman, living in an urban area, nonsmoker, diagnosed in 2006 in another service with Graves' disease. She was treated with variable doses of methimazole. The patient was admitted to our service in January 2014 for agitation, sinus tachycardia, significant weight loss, and diarrhea. The patient discontinued the treatment with ADTs for 10 months without consulting her physician. Hormone profile revealed severe thyrotoxicosis: TSH < 0.004 μUI/ml, FT4 = 4.88 ng/dl, FT3 = 21.1 pg/ml, positive antithyroid antibodies (AAT) and TRAb. Thyroid ultrasound: increased thyroid volume (40 ml), intense hypoechoic appearance “hell-like" vascularization. ECG: sinus tachycardia. Given the long course of Graves' disease, high thyroid volume and high TRAb levels, surgery was recommended. The preoperative preparation with Lugol solution 20 drops x 3/day for 9 days was initiated. Due to intercurrent respiratory infection surgery was delayed, but without discontinuing the administration of Lugol solution; the patient continued the administration of iodine solution at home for 30 more days. Readmitted for surgical treatment, the patient developed more severe symptoms of thyrotoxicosis (pulse = 140/min, intense sweating, agitation), the surgery being once again delayed, and the patient transferred to the Endocrinology Department. Clinical and laboratory assessments confirmed the diagnosis of Graves' disease; thyroid scan demonstrated the characteristic features of Jod-Basedow effect (large thyroid, highly increased thyroid uptake). Cardiac assessment: hyperkinetic heart, without signs of ventricular dysfunctions (fig. 1, 2).

The patient received treatment with high methimazole doses (Thyrozol 60mg/day), glucocorticoids (Prednisone 30 mg/day) and beta-blockers (Propranolol 40 mg x 2/day). Due to leukopenia (white blood cell count to 2730/μl) with neutropenia (neutrophil count to 920/ μl) methimazole administration was temporary discontinued and continued the administration of corticosteroids with gradual return to normal of leukocyte formula that allowed resumption of high ATDs doses. The clinical signs had progressively improved and the patient was discharged after 14 days. The surgical treatment was once again postponed, given the risk of thyrotoxic crisis. The patient was ambulatory monitored every 2 weeks. In April 2014 thyroidectomy was performed without preoperative preparation with iodine solution. The operative and postoperative courses were

uneventful. The patient developed postoperative hypothyroidism, and currently she is under thyroid replacement therapy. Histopathology confirmed the Graves' disease.

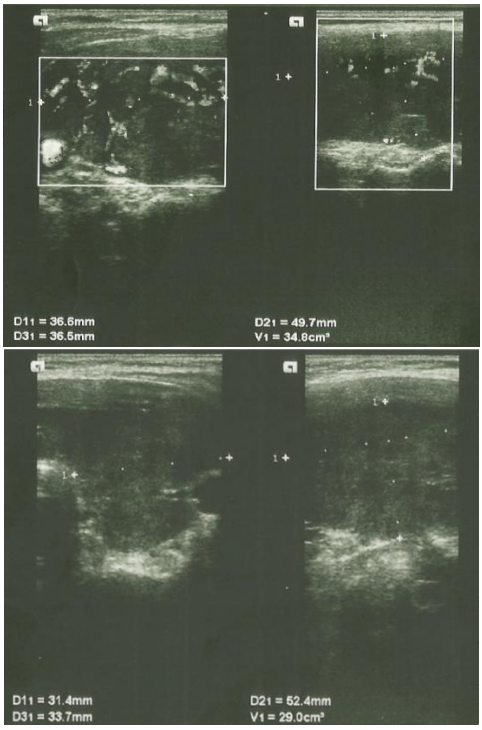

Fig. 1. Thyroid ultrasound showing an increased thyroid volume (63 ml), intense hypoechoic appearance, "hell-like" vascularization

Fig. 2. Thyroid scan: characteristic features of Jod-Basedow effect, large thyroid and highly increased thyroid uptake

DISCUSSION

In patients with Graves' disease treated for many years with ATDs, with an increased number of relapses, large goiter and high TRAb level, surgery may be a safe therapeutic option. Also, surgery provides rapid treatment and permanent cure of hyperthyroidism in most patients (8). Preoperative preparation of patients with hyperthyroidism to achieve euthyroid state is extremely important for avoiding perioperative complications due to severe thyrotoxicosis (13). This can be done using a combination of ATDs, beta-blockers and sometimes glucocorticoids (11). Thyroid storm is an exaggerated state of thyrotoxicosis that occurs in patients who have an inadequately treated thyrotoxicosis and a precipitating event such as thyroid surgery, with a mortality rate that has decreased over time from nearly 100% to approximately 20% in our days (4). Most surgeons administer iodine (as Lugol solution) to provide ≥ 30 mg of iodine/day for 10 days before surgery to decrease thyroid vascularity, the rate of blood flow, and intraoperative blood loss during thyroidectomy (12). These actions are explained by the Wolff-Chaikoff effect of excess iodine, an autoregulatory phenomenon that directly inhibits thyroid hormone synthesis and release. This effect lasts around 10 days, after which it is followed by an ”escape phenomenon”, with resumption of normal organification of iodine and normal thyroid function (14, 15).

In our patient, the preoperative preparation with Lugol solution was extended for a period of about 30 days (due to a misunderstanding), thus providing excessive amounts of iodine to the thyroid gland for a long period of time, and generating the so-called Jod-Basedow effect, with the exacerbation of thyrotoxicosis and risk of thyroid storm.

This condition has a steep onset with fever, marked tachycardia, and arrhythmias, which may be accompanied by pulmonary edema, congestive heart failure, gastrointestinal dysfunction, and central nervous system involvement (16,17). Knowledge of these aspects and careful monitoring of the patient are extremely important because the diagnosis is mostly clinical, the point at which thyrotoxicosis becomes thyroid storm being subjective (17). Even though some authors have proposed a clinical score to confirm the diagnosis, in current practice patients presenting with significant symptoms of thyrotoxicosis should be considered as being at risk for thyroid storm and undergo aggressive treatment, rather than waiting for a specific score threshold (17, 18). In our case, the patient presented an impaired general condition with aggravation of the cardiovascular, digestive and mental manifestations of thyrotoxicosis, thus prompt treatment with high doses of ATDs, beta-blockers, glucocorticoids and sedatives was initiated in an attempt to block the synthesis and peripheral conversion of thyroid hormones, and to control the clinical symptoms.

Besides minor adverse effects such as pruritus, skin rash, arthralgias, and slight elevations in liver enzymes levels, ATDs may rarely cause an aggravation of mild leukopenia that is common in Grave's disease, with risk of agranulocytosis (granulocyte count below 500/mm^3). Agranulocytosis may occur even in patients who previously tolerated ATDs, and multiple exposures may represent a risk factor for developing hematological disturbances (19, 20). This situation was met in our patient, who presented under methimazole a worsening of initial leukopenia, with granulocytopenia and risk of agranulocytosis, which forced us to temporarily discontinue the administration of ATDs, and continue only with glucocorticoids, which gradually normalized the absolute neutrophil count. Normalization of white blood count allowed us to resume the treatment with high doses of methimazole, in order to obtain a more rapid improvement of symptoms, by blocking the synthesis of thyroid hormones.

The clinical symptoms and hormone parameters gradually improved, and the patient was discharged after 14 days of hospital stay.

It is important to know that in thyrotoxicosis ATDs are blocking the thyroid hormone synthesis, not the release of preformed thyroid hormones. Euthyroidism is obtained only when intrathyroidal hormone and iodine stores are depleted, and this process requires up to 6 weeks. Large goiters with abundant deposits of thyroid hormone, especially when iodine excess is present, often show a delayed response to thioanmides (19, 21). In these circumstances, knowing the history of massive thyroid iodine load, confirmed by the increased scintigraphic uptake and the ultrasonographic aspect of the thyroid gland with high volume and intense vascularization, the surgical intervention was postponed again, due to the high risk of thyrotoxic crisis.

CONCLUSIONS

Our case highlights that although preoperative preparation with iodine solution is preferred by most surgeons in order to prevent complications during thyroidectomy, this treatment must be performed in hospital under close supervision by medical personnel, in order to avoid such complications like Jod-Basedow phenomenon and thyroid storm. Thus, surgery remains a safe therapeutic option for Graves' disease in many circumstances.

PHYSIOPATHOLOGICAL AND THERAPEUTICAL CORRELATIONS IN ALCOHOL DEPENDENCE

Andreea Silvana Szalontay

Discipline of Psychology and Behavioral Sciences

PHYSIOPATHOLOGICAL AND THERAPEUTICAL CORRELATIONS IN ALCOHOL DEPENDENCE (Abstract) No doubt, alcoholism represents nowadays the toxicomany with the highest expansion rate among all population groups, being recognized by the specialists from the medical, social, economic and legal field as a true "toxic pandemy". Researchers consider ethanol, this small but highly aggressive molecule, to have supremacy if we were to consider the number of pages dedicated to it worldwide on daily bases, in the medical or any other specialty literature. Nonetheless, the large volume of data regarding ethanol toxicity does not seen to simplify things, on the contrary it points out new information about the its negative effects on human body. Ethanol represents a toxic that is rapidly and completely absorbed in the intestinal tract being distributed to most tissues and organs; ethanol is recognized as an enzymatic inductor of its own metabolization but also of the metabolization of numerous therapeutic agents. **Keywords:** DEPENDENCE, ALCOHOL, TOXICOMANY, WITHDRAWAL, BEHAVIORAL CHANGES

The biological mechanism of alcoholism are still little known reason why it relies especially on hypotheses concerning, mainly, the disruption of neurotransmission after the action of ethanol on cellular membranes and neurotransmitters. The organism's sensitivity to this action seems to be, to a great extent, determined by genetic factors but, still, behavioral dependence represents the base of alcoholic toxicomany. Its origins indicate an organism predisposed to the consumption of alcohol combined with the availability of alcohol, their good social tolerance and low costs.

Physiopathological factors of physical dependence on alcohol

In general, it is considered to be three key factors involved in the complex phenomenon of the physical dependence on alcohol: intracellular metabolism; biological membranes and neurotransmitters which have constant interactions, especially at the level of neuronal transmission.

The effect of ethanol on intracellular metabolism. The main consequence of the use of alcohol is the considerable increase of the amount of H^+ ions in the cells and the increase of the NADH / NAD relation which regulates the intracellular oxido-reduction potential. The result is the alteration of oxygen consumption and of the activity of mitochondria and of the numerous enzymes that intervene in various metabolic processes. For counteracting these effects, progressive metabolic adjustments

appear: increased degradation of ethanol, enzymatic qualitative and quantitative (metabolic tolerance) adjustments (1).

During withdrawal, the fact that the NAHD / NAD relationship decreases brutally disturbs the cellular functioning, mainly that of the nervous cells, case that might influence the beginning of the withdrawal syndrome. Consequently, it is necessary to increase the basis for the brain protein synthesis during chronic alcoholism.

The effect of ethanol on biological membranes. Biological membranes are functionally active entities due to the molecular intra-membranous components. They regulate transmembranous exchanges and also intervene in certain intracellular metabolisms.

The membranous matrix consists of two layers of phospholipids to which numerous molecules are associated: proteins (hormonal receptors, enzymatic systems as the Na+ -K+ ATP-asis dependent, membranous transport systems) or glycoprotein (with role in cellular recognition, immune response) (1). For this system to work it is necessary:

- The physical condition of the membrane to be normal which is related to the lipids in the membrane and its mobility and it can be assessed by measuring the membrane fluidity;

- The membrane's biochemical condition to be normal, which is the distribution, the spatial structure and the activity of the membrane proteins is satisfactory as well as the lipid-protein interaction.

Modifications of the membrane's physical state

Nowadays it is known that a certain number of substances as detergents and general anaesthetics, including certain alcohols, have physical – chemical effects on the membranes.

Ethanol molecules are liposoluble and they can position themselves between the two layers of membranous phospholipids, conducting to the disorganization of the lipid matrix and the modification of the lipids lateral mobility and increase of membrane fluidity (1).

This effect depends of the dose, the same phenomenon being possible to appear *in vivo* conditions as well, disrupting the fluidity or the optimal micro-viscosity which is essential to the well functioning of the cells. In case of chronic intoxication there is the possibility of cell adjustment which manifests itself as tolerance to alcohol, with insufficiently identified mechanisms (2). Cells seem to be capable to increase the incorporation of saturated fatty acids and to diminish the ratio of unsaturated fatty acids. Another possibility would be the increase in cholesterol content at the level of the membrane, transmethylation, modification of protein synthesis etc. The result consists in lipid rearrangement which strengthens the structure and increases the stiffness of the membrane which diminishes penetration and the fluidizing action of ethanol (just like of all liposoluble molecules, which partly explains the well known resistance of alcoholic patients to general anaesthetics).

During withdrawal, the break of the new biological balance due to the disappearance of the fluidizing effect of ethanol will be responsible for the apparition of the temporary hyper viscosity of the membrane which will disrupt its functioning until the physiological structure is re-established.

Modifications of the membrane's biochemical state

Ethanol is also capable of modifying the

functioning of membrane proteins (enzymes, transport proteins, receptors, surface glycoproteins) but it is important to point out that their answer depends to a great extent of: the proteins involved (for ex. Ca^{2+} dependent ATP-ase seems a lot more sensitive to the action of alcohol than Na^{+} - K^{+} ATP-ase dependent; protein localization, the kinetic features of the receptors seem to vary depending of the cerebral area and the genetic factors which have an important role in adjusting and establishing the sensitivity to effects of ethanol.

Enzymes. Until now there are few studies dealing with the alteration of *biochemical membrane processes* under the action of ethanol. Na^{+} - K^{+} ATP-ase dependent is the most studied enzyme as it intervenes in the active transport of sodium and potassium ions and maintaining their transmembranous gradient (1, 2).

In vitro studies have shown that after the administration of large doses of ethanol this enzyme is inhibited while after the administration of small doses of ethanol it becomes active.

This effect can explain the behavioural modifications induced by ethanol and it can be caused by the disruption of protein microenvironment consequent to phospholipids alteration accompanied by the modification of both spatial configuration and their activity (3).

Calcium, with a key role in membranous stability, in controlling intracellular signals and so in neurotransmission, is also disrupted by ethanol.

In case of chronic intoxication there is an increase of the calcium content in the synaptosomal membranes which seems to be the consequence of long term adjustment to ethanol effects.

Receptors, membrane proteins with particular specificity and affinity features for certain molecules can act at membrane level by coupling with an ionic channel or / and through intracellular syntheses, especially enzymatic, acting on the protein synthesis or on certain metabolisms.

The most famous system is the adenyl cyclase functioning unit – AMP cyclic protein kinase which intervenes mainly in the transmission of catecholaminergic signals. Ethanol disrupts the activity of this complex system either by modifying the physical structure of the surrounding environment of proteins, or by acting at the level of the regulating systems: calcium or/and calmodulin (calcium dependent activation protein). During the beginning of ethanol dependence it seems to be an increase in the sensitivity of the receptors at catecholamines. This can be due to the adjustment of the postsynaptic receptors to the activity of the presynaptic systems and to the effects of ethanol at membranous level (1, 3).

During withdrawal it was experimentally demonstrated the diminished answer of adenyl cyclase to the stimulation with dopamine. This decrease of sensitivity can also be pointed out at adrenergic ß receptors. This effect is inconsistent and depends of the brain area taken into consideration: present in the striatulum, it is absent at mesolimbic level because of the different characteristics receptors have in these two regions (4). The effect disappears if the laboratory animals are given sufficient amount of alcohol, which demonstrates that this system has become dependent on alcohol.

Another factor involved in the development of physical dependence on alcohol is represented by *neurotransmitters*, *acetylcholine* being the most widespread in the

central nervous system, it is heterogeneously distributed and acts on the muscarinic and nicotinic receptors (1, 4).

Ethanol definitely affects the cholinergic transmission; at very high concentrations of alcohol there will be an increased activity of acetylcholine transferase (which intervenes in the synthesis of acetylcholine) while the activity of acetylcholinesterase (degradation) is diminished. The release of acetylcholine is also disrupted (1, 5).

We must underline that that cholinergic system, especially at the level of the striated system is controlled through the D2 receptor of dopamine, the receptors can be affected by alcohol so that the muscalinic type cholinergic receptors undergo certain modifications during alcohol intoxication (2, 5).

The sensitivity of acetylcholine stands for the adapted answer to the effect of ethanol, but it is difficult to establish the eventual role of the cholinergic system, of the parasympathetic one in particular, during the withdrawal syndrome.

Noradrenaline acts through two families of postsynaptic ß receptors (ß1 and ß2) which connect to adenyl cyclase and α, presynaptic (α_1) and postsynaptic (α_2) which are not connected to adenyl cyclase. Presynaptic receptors in association with neuromodulators (dopamine, GABA, endogenous opioids) regulate the synthesis and the release of noradrenalin. The role of this extraordinarily complex noradrenergic system consists in the modulation of the information arriving at the level of the projection systems.

The action of alcohol on noradrenalin and dopamine has been intensely studied but the results are highly contradictory. It appears that the acute administration of ethanol increases the urinary secretion of catecholamine stimulating thus their release at the level of the suprarenal (stress effect). Some experiments demonstrate that *in vitro*, ethanol diminishes synaptic release, reuptake and the renewal process of catecholamines. Some authors have demonstrated the biphasic structure of this effect: increased release and renewal process in a first phase followed by decrease (according to the behavioural effects of ethanol) (2, 4).

The studies conducted during chronic intoxications are more conclusive. They all underline the increasing renewal percent of noradrenalin and dopamine, as well as their synthesis by stimulation of tyrosine hydroxylase. Their release will be just as intense. All these elements certify the increased functional activity of the neurons which can be due to their adjustment to the depressive effects of ethanol.

Serotonin acts through two types of receptors, 5HT1 and 5HT2, with different locations and with different pharmaceutical features. Even if modifications appear, in particular a decrease of brain serotonin that has been invoked in the apparition of tolerance and dependence, it is difficult to point out an effect of alcohol on serotonin, during both acute and chronic phase. Some authors have identified a low level of serotonin during the acute phase and a higher one (due to the adjustment), as a consequence of chronic alcoholism.

There is the possibility that the alteration of serotonin receptors play a role in the appearance of physical dependence. Finally, just like in the case of catecholamine, the disruption of metabolization paths is possible. Thus, the excretion of 5-hydroxytryptophol a compound resulted from the reducing path, increases. Its association with acetilaldehyde will lead,

through various cycles, to the formation of molecules capable of acting at the level of the central nervous system, the β carbolinic acids (3).

β carbolinic acids stimulate the noradrenergic system and they are anxiogenic substances, causing nervousness and favouring the apparition of convulsions, which disappear after the administration of diazepam. The increase of endogenous synthesis of this type of molecules during chronic alcoholism might, consequently, facilitate, if not explain the clinical manifestations recorded during withdrawal.

The gamma-aminobutyric acid (GABA) is widely spread al cerebral level, approximately 30% of brain synapses being GABAergic. Due to its inhibiting feature, it is present mainly in the fast neural circuits, at the level of inhibiting neurons. GABA plays an important role in regulating catecholaminergic systems, inhibiting especially the extrapyramidal dopaminergic and mesolimbic function. Experimentally, an increased level of cerebral GABA diminishes the induced convulsive activities regardless on the induction method.

Various studies dealing with the action of ethanol on the GABA level have contradictory results which seem to be caused by the various protocols used and by the sensitivity differences between the dosing methods (5).

In case of acute intoxication, the GABA level appears to be normal or high, the blocking of Krebs cycle through the excess of H^+ ions having the tendency to increase the level of glutamic acid and GABA, while in case of chronic intoxication, the GABA level is normal or low (4, 5).

During withdrawal, GABA is frequently low. Moreover, alcoholic patients experiencing convulsions seem to have the GABA level in the cephalorachidian liquid smaller if compared to the witnesses. GABA interacts with a complex system of receptors including at least three different sites: GABA receptor, benzodiazepine receptors (one, connected to the chloride channel, is responsible for the anxiolytic and convulsive action of benzodiazepine, the other, regardless of the chloride channel, induces the other features of benzodiazepine, especially the sedative effect) and the receiving site for picrotoxin, the exciting substance that blocks the GABAergic transmission without modifying the attachment of GABA on its receptor.

The inhibition of the GABAergic transmission explains, at least to some extent, the hyper excitability responsible for the apparition of trembling and convulsions during the withdrawal period, the injection of GABA or agonists attenuating or even suppressing these manifestations while its antagonists emphasize them.

Alcohol can, just as much, determine the disruption of benzodiazepine receptors, phenomenon present only for moderate concentrations and it disappears at large amounts of alcohol. In the clinic it can be underlined the potentiating effect of the association of alcohol and benzodiazepine.

In case of chronic alcoholism, the site of picrotoxin can be equally altered by ethanol decreasing the attachment capacity (3).

Endogenous opioids: are substances from the human body whose physiological action is accomplished through various receptors, determining different pharmacological answers. Thus, peripherally, enkephalins inhibit the release of P substance, transmitter of painful signals, and at central level, numerous aminergic structures, especially dopaminergic, are subjected to the control of opioids. At the level of

the hippocampus, enkephalins have an exciting effect: determine the increase of spontaneous release of pyramidal cells and facilitate the release of neurotransmitters inhibiting GABA through the neighbouring inhibiting interneurons.

Ethanol stimulates the release of endogenous opioids, fact witnessed by their plasmatic and intracerebral level. This answer might be on the other hand related to the stress caused effect which induces the suprarenalian and cerebral release of catecholamines and enkephalins and the hypothalamic - hypophysarian secretion of β endorphin and stress hormones, prolactin and especially ACTH. This release might intervene, but only partially, in ethanol dependence.

Much more interesting is the study of the action of ethanol on the functional activity of opioergic systems. It was suggested that the modifications of dopamine metabolism are not due to a direct effect of ethanol but to an action of the enkephalinergic systems. It might be an increase of endogenous enkephalins, at least in some brain regions, but also the action of false neuromediators as tetra isoquinolines on receptors or a modification of the sensitivity of these receptors. It appears that the alteration of the opioidergic systems plays an important role in alcohol tolerance and dependence. In case of chronic administration of alcohol, the adjustment phenomena come into action, interesting the membranes and the secretion of endogenous opioids which will be low (2, 5).

Behavioral dependence. The abusive self administration of a substance relies at the base of the notion of behavioural dependence which can be motivated by a certain emotional condition or motivation; the presence of certain information necessary in triggering the behaviour; the beginning of a learning process; the existence of a voluntary decision to authorize and order the fulfilment of the behaviour.

Two fundamental brain areas intervene in these different phases: the neocortex, the centre of decision and dominating voluntary commands and the paleocortex, which lays at the basis of the state of need and of the learning processes due to the existence of sensorial analysis and memorization systems.

In case of alcohol dependence, the condition is not irreversible as the development of a motivation can allow the reestablishment of the normal control process at the level of the neocortex with the possibility of achieving withdrawal and abstinence.

The consumption of alcohol is induced by external, social-cultural factors and/or for the achievement of pharmacological effects. The perpetuation of this behaviour depends of the continuous presence of external factors, the development of physical dependence and the achievement of pharmacological effects, often being used for overcoming conflict situations which isolated can lead to the development of conjunctural, intermittent alcohol dependence.

CONCLUSIONS

There are numerous neurotoxic substances, alcohol being one of them, capable of determining functional perturbations on the nervous system (functional neurotoxicity) or lesions (structural neurotoxicity).

The word “alcoholism” evokes a particular behavior characterized by the dependence of repeated self-administration of alcohol. This fact requires first of all the existence of an initial impact between a toxic (alcohol) and a predisposed, vulnerable organism. This particular individual

receptivity, possibly genetically determined expresses itself better if the surrounding environment and the social cultural context are favorable.

A NOVEL MOUSE MODEL OF SOFT-TISSUE INFECTION USING BIOLUMINESCENCE IMAGING ALLOWS NONINVASIVE, REAL-TIME MONITORING OF BACTERIAL GROWTH

A recent study conducted by Yoshioka K. and collaborators from Japan successfully established a real-time, in vivo, quantitative mouse model of soft-tissue infection in the superficial gluteus muscle (SGM) using bioluminescence imaging. A bioluminescent strain of MRSA was inoculated into the SGM of BALB/c adult male mice, followed by sequential measurement of bacterial photon intensity and serological and histological analyses of the mice. The mean photon intensity in the mice peaked immediately after inoculation and remained stable until day 28. The serum levels of interleukin-6, interleukin-1 and C-reactive protein at 12 hours after inoculation were significantly higher than those prior to inoculation, and the C-reactive protein remained significantly elevated until day 21. Histological analyses showed marked neutrophil infiltration and abscesses containing necrotic and fibrous tissues in the SGM. With this SGM mouse model, they successfully visualized and quantified stable bacterial growth over an extended period of time with bioluminescence imaging, which allowed them to monitor the process of infection without euthanizing the experimental animals. This model is applicable to in vivo evaluations of the long-term efficacy of novel antibiotics or antibacterial implants. (Yoshioka K, Ishii K, Kuramoto T, Nagai S et al. A Novel Mouse Model of Soft-Tissue Infection Using Bioluminescence Imaging Allows Noninvasive, Real-Time Monitoring of Bacterial Growth. *PLoS One* 2014 Sep 3. PMID: 25184249).

METABOLIC DISORDERS IN PATIENTS OPERATED FOR PANCREATIC CANCER (Abstract): Adenocarcinoma of the pancreas presents a major threat with a 5-years survival rate of 5%. Whipple pancreaticoduodenectomy (PD) is the standard procedure for cephalopancreatic neoplasm. After an extended resection and reconstruction of superior gastrointestinal tract the digestive physiology might be heavily disrupted. A literature review of metabolic alterations of patients who suffered a major pancreatic resection is performed, regarding micronutrients, lipid absorption and pancreatogenic diabetes. Long-term survivors following PD generally have a satisfactory nutritional status although with subclinical iron, vitamin D and selenium deficiency. These patients should be followed-up also regarding these micronutrients and properly dietary supplemented when necessary, also considering the increased life expectancy. Approximately 17-25% of patients will develop insulin-dependent diabetes but pancreatogenic diabetics have elevated levels of serum insulin and minimal or absent response to food intake, as opposed to a type I diabetics, where insulin serum is normal or elevated and there is an exaggerated response to ingestion of sugar. **Keywords**: PANCREATIC CANCER, SURGERY, METABOLIC, NUTRITIONAL, DIABETES

Adenocarcinoma of the pancreas is a major threat to survival, worse than most other forms of gastrointestinal cancer (1). Compared to other gastrointestinal malignancies, exocrine pancreatic cancer is a fairly common malignancy, outnumbered only by colorectal cancer and – slightly – by stomach cancer. Pancreatic ductal adenocarcinoma is the most common malignancy of the pancreas, most frequently arising from the ductal epithelium of the pancreas (2). The age adjusted incidence rates peaks between 60 and 80 years which implies that many of the patients are not fit enough for extensive surgery (3).

Until 1970s, pancreaticoduodenectomy (PD) was a seldom performed procedure, which should be understood against a backdrop of in-hospital mortality of 20-25 percent. However, during the 1980s and 1990s,

experience in performing PD increased steadily and high-volume centers reported low treatment-related morbidity and mortality. One rationale for the increased rate of TP may be an increased diagnosis of diffuse ductal disease in all patients undergoing pancreatic resection. Improved radiographic and endoscopic surveillance during preoperative testing as well as close attention to intra-operative frozen section pathologic analysis of the pancreatic duct margin may contribute to this.

Recently the mortality in high-volume centers is usually close to zero, whereas major morbidity has decreased to 30% or less – even though the procedures have been extended (4). Depending on the stage, the treatment options include chemotherapy, radiation, and surgery. Surgical resection has offered the only hope for cure in the treatment of exocrine pancreatic cancer. Even so, pancreatic cancer still remains a major, unsolved therapeutic challenge and is the most lethal type of gastrointestinal cancer with a 5-year survival rate of 5%. Adjuvant chemotherapy remains to be gemcitabine alone, though fluorouracil offers the same survival and role of radiation remains controversial. Nevertheless, only a few patients survive for at least 5 years after R0 resection and adjuvant therapy (5). Generally, one of the reasons for the bad prognosis of pancreatic cancer is the late diagnosis despite the development of new technologies. This delay in diagnosis is mainly due to the fact that there is no early symptom or sign. Moreover, the initial presenting symptoms of pancreatic carcinoma are generally vague and non-specific.

The development of sophisticated surgical procedures, improved postoperative care, and the capacity for early diagnosis of disease has prolonged life expectancy after pancreatic resection.

Whipple PD is the standard procedure for neoplasm of duodenum, ampulla of Vater, distal coledochus and the head of pancreas. After an extended excision and reconstruction of superior gastrointestinal tract, the digestive physiology might be heavily disrupted. Previous studies have shown that patients might maintain a normal body mass index (BMI) after surgery for pancreatic cancer, although frequently lower than preoperative values (6, 7, 8).

Metabolic disorders consecutive to pancreatic resections have not been widely studied. Compared to healthy individuals, these patients may have measurable reduced concentrations of trace elements and vitamins (selenium, vitamin B12, vitamin D) in whole blood and serum by the time cancer is diagnosed and long before clinically relevant changes in nutritional status are seen (9). Armstrong et al. showed that long-term survivors of duodenopancreatectomy are relatively deficient in several micronutrients compared to non-operated controls taking the same diet. Patients had elevated transferrin and low ferritin levels indicating relative iron deficiency. Patients also showed lower levels of the anti-oxidants -selenium and vitamin E- with 57% of patients with significant selenium deficiencies. Lower levels of vitamin D than controls were found and 30% of patients had a high parathyroid hormone level, suggesting compensatory mechanisms operate to maintain normocalcaemia (10).

The two important antioxidants in the diet, selenium and vitamin E, have an important role in anti-inflammatory reaction and also are protective factors in heart diseases, infectious diseases and in neoplastic processes. After PD 57% of the patients had selenium deficiency which in advanced stages can lead to cardiomyopathy. Although vitamin E level was significantly lower in operated patients, it remained at normal values. It's already

known that the deficit of antioxidant agents contributes to the progression of pathophysiological processes in chronic pancreatitis so we consider that low values of selenium and vitamin E should be avoided in patients operated for pancreatic cancer. Other micronutrients such as copper and zinc which are part of many metalloenzymes and normally play an important role in cell mediated immunity have low values in patients operated for pancreatic cancer. These observations did not have an impact on infection rates so that these changes have no clinical relevance.

In addition to improved endocrine control, exocrine insufficiency may be improved by modern pancreatic enzyme formulations, proton pump inhibitor therapy and the use of the duodenum-preserving pancreatic head resections. In a report from Japan, the pylorus-preserving technique was noted to be associated with significantly improved albumin levels and weight loss over the standard total pancreatectomy (21).

Lipid malabsorption after major pancreatic resections is the result of several mechanisms contributing to early occurrence of steatorrhea compared malabsorption of other nutrients. For various reasons impairment of pancreatic lipase activity cannot be sufficiently compensated by other mechanisms. Digestion of fats in the small intestine is mainly due to the combined effects of lipase and its cofactors, especially bile acids. Intestinal mucosa does not express enzymatic systems that digest triglycerides and lipolytic activity performed by other extrapancreatic sources (salivary and gastric) cannot compensate lipid digestion by pancreatic lipase (11).

The loss of pancreatic parenchyma resulting from pancreatic resection causes an extreme disruption of glucose homeostasis known as pancreatogenic diabetes.

Pancreatogenic diabetes is attracting attention as the primary factor influencing quality of life in patients who have undergone this procedure, but is difficult to predict the effect on carbohydrate metabolism because metabolic changes are from mild to major. The incidence of new-onset diabetes mellitus after pancreatic resection increases as the follow-up period after surgery becomes longer and is related to the progression of underlying disease, the type of surgery, and the extent of resection. In general, postoperative changes are usually moderate to severe and approximately 17-25% of patients will develop insulin-dependent diabetes.

Studies on pancreatic endocrine function after resection are few and controversial. This is probably due to the fact that long-term metabolic consequences may differ even if for the same type of pancreatic resection or surgical indication and depend mainly of the quality of the remaining pancreas tissue (tab. I).

TABLE I

Postoperative consequences after different types of resection and drainage procedures for pancreatic cancer

Distal pancreatectomy	New diabetes	21-40%	Morrow(12)
Cefalic pancreatectomy with presevation of the duodenum	New diabetes	2-15%	Beger(13)
Cephalic pancreatectomy with preservation of the pylorus	New diabetes	12%	Traverso(14)
Whiple duodenopancreatectomy	New diabetes	17%	Schwarz
Total pancreatectomy	Brittle diabetes	100%	Andrén-Sandberg (15)

The pathophysiology of pancreatogenic diabetes is related to pancreatic hormone deficiency and the altered responses of the liver and peripheral organs to lower than normal hormone levels. Experimental results suggest that insulin-independent glucose metabolism after pancreatic resection is done for a large proportion of absorbed glucose. This may explain why patients with pancreatogenic diabetes behave differently than other diabetics sensitive to insulin therapy. These patients with unmanageable diabetes - "brittle diabetics" - may become unpredictable hypoglycemic during treatment with insulin, unrelated to food intake or to physical effort. Diabetes resulting after pancreatic resection differs in several ways from type I (juvenile, or insulin-dependent) and the type II (adult, or non-insulin-dependent).

Hyperglycemia occurs when the amount of insulin produced or administered is insufficient because of unsuppressed hepatic glucose production secondary to a deficiency in pancreatic polypeptide.

In contrast, patients lapse into hypoglycemia when insulin is barely excessive because of enhanced peripheral insulin sensitivity and glucagon deficiency. Nutritional state, pancreatic exocrine function and intestinal function also affect glycémic control. Unlike type I diabetes, patients with pancreatogenic diabetes rare develop ketoacidosis and the degree of hyperglycemia is mild in most cases. Compared with type II diabetes highly resistant to insulin, resected patients are really sensitive to insulin and iatrogenic hypoglycemia episodes are common. These patients have an increased serum level of gluconeogenetic precursors such as lactate and alanine (16). These distinct clinical and metabolic aspects have been attributed to pancreatic glucagon secretion deficits (17).

Pancreatogenic diabetics have elevated levels of serum insulin and minimal or absent response to food intake, as opposed to a type I diabetics, where insulin serum is normal or elevated and there is an exaggerated response to ingestion of sugar (18) (tab. II).

TABLE II

Pancreatogen diabetes, post resection diabetes, compared to classical forms of diabetes

Variables	Type I diabetes	Type II diabetes	Pancreatogenic diabetes
Ketoacidosis	frequent	rare	rare
Hyperglycemia	severe	mild	mild
Hypoglycemia	frequent	rare	frequent
Peripheral insulin sensitivity	normal/elevated	low	elevated
Liver insulin sensitivity	normal	elevated	low
Insulin level	low	elevated	low
Glucagon level	normal/elevated	normal/elevated	low
Pancreatic peptide level	elevated	elevated	low

As pointed out by Frey et al., the incidence of diabetes is directly related to the extension of the resection of pancreatic tissue (19). Patients requiring total or near-total pancreatectomy pay a significant price represented by altered secretion of glycemic regulating hormones. In these patients requiring distal pancreatectomy or only a

limited excision of the pancreas diabetes develops far less frequently than those that require PD or total or near-total pancreatectomy.

It has been noticed an increased sensitivity of extrahepatic tissue to psysiological hyperinsulinemia and increased amounts of insulin binded to receptors from red blood cells in patients with pancreatogenic diabetes. Thus, there is an increase of peripheral insulin receptors in response to insulin deficiency that makes these patients susceptible to hormone replacement.

Patients with PD have a good metabolic status and a significant number of them require insulin replacement therapy, due to failure to control blood sugar with oral antidiabetic agents. Insulin replacement is considered to be the main treatment option for insulin dependent pancreatogenic diabetes. Improvements in glucose monitoring systems, insulin delivery systems and insulin formulations may contribute to superior glycaemic control for these patients. (25)

Surgeons, gastroenterologists and endocrinologists alike may be more comfortable with the management of the apancreatic state that was so feared in the past. Jethwa *et al.* (22) reported that there were no observed mortalities as a result of diabetic complications or metabolic consequences of pancreatic resection during long-term follow-up of 47 patients undergoing TP. They concluded that diabetic control after TP is less difficult and associated with fewer glycaemic complications than generally assumed. Similarly, in the largest single institution review of 124 elective TPs, a group from Germany found TP was performed with the same morbidity rate as partial pancreatectomy, and quality of life was not significantly different in the two groups. (23) This confirmed a previous report from 2005 where quality of life in 34 TP patients was compared with matched type I diabetic controls, and no difference was found. (24)

The significant metabolic derangements of the apancreatic state may not become immediately apparent in the post-operative inpatient recovery phase. Most of these elderly patients do not have baseline endocrine or exocrine insufficiency before surgery and have difficulty adjusting to complex diabetic and nutritional changes seen after TP. Multidisciplinary management is mandatory for improved outcomes and intensive diabetic and nutritional counselling are essential. Providing extended care by discharge to a skilled nursing facility with diabetic education and nutrition capabilities appears appropriate. Additionally, consideration should be given for providing all patients with supplemental enteral feeding for several weeks post-operatively. A strict follow-up protocol should be available for these patients who include close endocrine and nutrition supervision, strict adherence to proton pump inhibitor (PPI) and pancreatic enzyme replacement therapy and adequate hydration and protein intake. These measures may avoid readmission in the majority of the patients, particularly for the diagnosis of dehydration, diabetic complications and failure to thrive (26).

CONCLUSIONS

Mortality and long-term morbidity associated with TP appear to be lessening over the past decade, indicating that the risks of TP appear acceptable compared with the benefits of resection, especially for those patients with premalignant disease. Overall, survival is generally based on the underlying disease process, not a consequence of the surgery.

The goal of the treatment of pancreatic

cancer should be to balance the quantity and quality of life according to individual preferences. Long-term survivors following PD generally have a satisfactory nutritional status although with subclinical iron, vitamin D and selenium deficiency. These patients should be followed-up also regarding these micronutrients and properly dietary supplemented when necessary, also considering the increased life expectancy.

SYNDROME-ASSOCIATED SOFT TISSUE TUMOURS

Soft tissue neoplasms may be associated with a variety of genetic disorders and malformation syndromes, especially when they arise in children, adolescents and early adulthood. While many soft tissue tumours are sporadic and without a known pathogenesis or established risk factors, in recent years there has been an increasing awareness that certain types of benign, intermediate and malignant soft tissue neoplasms may be a manifestation of a genetic or malformation syndrome and that specific syndromes carry with them a higher risk of sarcoma. This is a particular concern for children, adolescents and young adults because of the relatively increased frequency of sarcomas in younger patients. Li–Fraumeni syndrome (including those with germline p53 mutations), hereditary retinoblastoma and neurofibromatosis type are the prototypical syndromes associated with soft tissue tumours, but many other syndromes and genetic conditions have soft tissue tumours as a manifestation, including Gorlin–Goltz syndrome, familial adenomatous polyposis (FAP) and pleuropulmonary blastoma syndrome. Vascular masses, usually malformative in nature, are characteristic of a variety of other disorders, including Maffucci, Sturge–Weber, Klippel–Tr_enaunay–Weber, Proteus and von Hippel–Lindau syndromes. In children, malformation syndromes, congenital anomalies and genetic disorders are among the major risk factors for development of soft tissue sarcoma. In this review, the authors summarize the principal histopathological types of soft tissue tumours which occur in various syndromes, with an emphasis on pathological features, genetic aspects and considerations for the diagnostic pathologist (Coffin C M, Davis J L & Borinstein S C. Syndrome-associated soft tissue tumours. Histopathology 2014, 64, 68–87).

EFFECTS OF SOME DOPAMINE ANTAGONISTS ON SPATIAL MEMORY PERFORMANCE IN RATS - EXPERIMENTAL RESEARCHES (Abstract)**:** Dopamine is a neurotransmitter with an important role in forming long-lasting memories for some time, especially in episodic memory. Literature data show that dopamine receptor stimulation may be detrimental to spatial working memory functions in lab animals. (R)-(+)-7-Chloro-8-hydroxy-3-methyl-1-phenyl-2,3,4,5-tetrahydro-1H-3-benzazepine hydrochloride derivative - SCH-23390 is a synthetic compound that acts as a selective, high-affinity antagonist of D1 receptors. Experimental studies suggest that SCH 23390 may prevent the spatial working memory disturbances induced by the active substances of marijuana. Melperone is an atypic antipsychotic drug presenting also dopaminergic D2 and 5-HT2A receptor antagonistic activity. This neuroleptic agent is used in the treatment of some types of schizophrenia. **Aim:** Experimental research on the effects of two dopamine receptor antagonists on spatial memory performance in rats. **Material and methods:** The experiment was carried out in white Wistar rats (200-250g), divided into 3 groups of 7 animals each, treated intraperitoneally with the same volume of solution for 14 days, as follows: Group I (Control): saline solution 0.1ml/10g kbw; Group II (coded SCH): SCH-23390 0.3 mg/kbw; Group III (coded MLP): melperone 2 mg/kbw. The dopaminergic agent spatial memory performance was assessed by recording spontaneous alternation behavior in a single session in Y-maze. Each animal was placed at the end of one arm and allowed to move freely through the maze during an 8 min session. Alternation was defined as a consecutive entry in three different arms. The alternation percentage was computed with the following formula: number of alternations divided by total number of arm visits minus 2. Data were presented as +/- standard deviation and significance was tested by SPSS Statistics for Windows version 13.0 and ANOVA method. P-values less than 0.05 were considered statistically significant compared to those in the control group. Experimental researches were carried out in compliance with the regulations of our University Committee for Research and Ethical Issues. **Results:** SCH-23390 (0.3 mg/kbw) and melperone (2 mg/kbw) intraperitoneal injection for 14 days determined a statistically significant ($p<0.05$ and $p<0.01$, respectively) increase in spontaneous alternation rate (compared to controls in Y-maze test). **Conclusions:** Our research revealed that the 14 consecutive days administration of these two dopamine receptor antagonists was associated with the improvement of short-term memory in rats, more intense for SCH-23390 compound. **Keywords:** SCH-23390, MELPERONE, Y-MAZE TEST, MEMORY

Substances mediating dopaminergic transmission have been clinically used in the treatment of different neurological and psychiatric disorders such as Parkinson and Huntington disease, schizophrenia, bipolar disorder, attention deficit hyperactivity disorder. Dopaminergic system, have been also known to play a major role in the emotional response to rewarding, as well to aversive stimuli (1).

SCH-23390 is a R)-(+)-7-Chloro-8-hydroxy-3-methyl-1-phenyl-2,3,4,5-tetrahydro-1H-3-benzazepine hydrochloride derivative acting as a selective, high-affinity antagonist of D1 receptors. Experimental studies have shown that SCH 23390 abolished generalized seizures induced by the chemoconvulsants: pilocarpine and soman (2, 3).

Melperone is a dopaminergic D2 and 5-HT2A receptor antagonist. This butyrophenone derivative structurally related to haloperidol has the ability to produce an antipsychotic effect in man at doses that cause minimal extrapyramidal side effects (4). It is also known to possess anxiolytic properties (5).

Electrophysiological studies showed that this drug determined an increase of dopamine levels in the medial prefrontal cortex and nucleus accumbens and a release of acetycholine in the medial prefrontal cortex. Clinical trial revealed that melperone is used especially in the treatment of neuroleptic-resistant schizophrenia (6, 7).

The supposition that dopaminergic system is involved in modulation of recognition memory is based on different experimental reports indicating the enhancement of memory consolidation by activation of dopaminergic receptor (8).

To directly prove this hypothesis we investigated the effects of two dopamine receptor antagonists, SCH-23390 and melperone, on spatial memory performance in Y-maze, a behavioral test for measuring the eagerness of lab animals to explore new environments.

This standardized test is used to evaluate working memory in rodents by measuring spontaneous exploratory behavior. The substances were administered one hour before the beginning of a behavioral session.

MATERIAL AND METHODS

Male white Wistar rats (150–200g) were used in the study. Animals were housed in plastic cages in an animal room maintained at 23 ± 1°C on a 12-hour dark cycle (light period, 07:00-19:00).

Animals had water *ad libidum* and were maintained at 85% of their free feeding weight by controlling the amount of their single daily meal following the experimental session during 45 min. Before the experiment, rats were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

The animals were distributed into 3 groups of 6 subjects each, and treated intraperitoneally as follows Group: I (Control): saline solution 0.1ml/10 kbw; II (coded SCH): SCH-23390 0.3 mg/kbw; III (coded MLP): melperone 2 mg/kbw.

The used drugs, SCH-23390 and melperone (Sigma-Aldrich Chemical Company), were dissolved with 0.9% saline, prepared immediately before use. All drugs were injected intraperitoneally in a constant volume of 0.1 ml/10 g body weight.

To assess the possible involvement of dopamine agents in the maintenance of spatial cognition, the present study investigated the effects of dopamine receptor antagonists SCH-23390 and melperone on rat memory performance on Y-maze (9). This device consists of 3 identical arms (40

x 9 x 16 cm) situated at 120° from each others, and a central triangular platform. Each arm has walls with specific motifs all over the inner area of the three walls allowing animals to distinguish it from the others.

This experimental model was used to tests if the rat remembered the arm it had just explored and would therefore enter one of the other arms of the maze. Each animal was placed at the end of one arm and allowed to move unreservedly through the maze during an 8 min session. The first 2 minutes were for habituation, and the last 6 minutes for the alternation between arms recorded with photo beam breaks positioned at midpoint of each arm. Repeated activation of the same detector was not considered as an arm-entry until the detector in another arm was activated.

Spontaneous alternation was defined as entry to an arm that was least occupied in recent times (10). Latency to leave the start arm, latency of first arm visit, number of arm visited, alternate arm returns, and the same arm returns were also counted.

A video camera set over the device and connected to a computer in another room was used to allow us to score behavior without distressing the animals. All trials were videotaped and analyzed by an observer unfamiliar with treatment condition. The tasks were performed between 8:00 and 13:00 a.m.

Data for each measure were evaluated separately by analysis of variance for repeated determinations. Results were expressed as arithmetic mean ± SD and represented graphically. All values were processed using SPSS for Windows version 17.0 and ANOVA method. P-value less than 0.05 were considered statistically significant compared to controls.

Experimental protocol was implemented following the recommendations of the "Grigore T. Popa" University Committee for Research and Ethical Issues guidelines for the handling and use of experimental animals, according to the ethical standards of the European Community.

Each animal was used once only and the duration of the experiments was kept as short as possible. For ethical considerations all the animals were sacrificed at the end of the experiment (11).

RESULTS

Spontaneous alternation or free-running in rats refers to their natural tendency to spontaneously choose alternate arms in a Y-maze. Arm exploration was defined as entering at least the first third of an arm. The alternation percentage of saline-treated rats was 61.4 ± 2.28.

Intraperitoneal administration of SCH 22390 resulted in a decreased e number of arm entries (mean ± S.E.M. number of arm entries was 22.67±1.63), but statistically non-significant compared to control animals (mean ± S.E.M. number of arm entries was 28.17±2.14) (tab. I).

The 14-day treatment with SCH-23390 (0.3 mg/kbw) determined a 77.2±1.72 spontaneous alternation rate.

Statistical analysis of the results showed that the alternation rate of SCH-23390-treated rats was statistically ($p<0.05$) higher than that of control rats in Y-maze test, thus suggesting a facilitation of extinction learning (fig. 1).

The administration of melperone (2mg/kbw) resulted in a statistically significant ($p<0.01$) increase of spontaneous alternation rate (86.8±1.16) compared to controls, suggesting effects on spatial memory, especially on short-term memory (tab. II, III).

TABLE I

Descriptive statistics - Spontaneous alternation rate

	N	Mean	Std. Deviation	Std. Error	Min	Max
Controls	6	61.40	2.28	.206	58.40	64.50
SCH-23390	6	77.20	1.72	.118	75.70	80.50
Melperone	6	86.80	1.16	.154	85.70	88.90

* The mean difference is significant at the .05 level.

* The mean difference is significant at the .05 level.

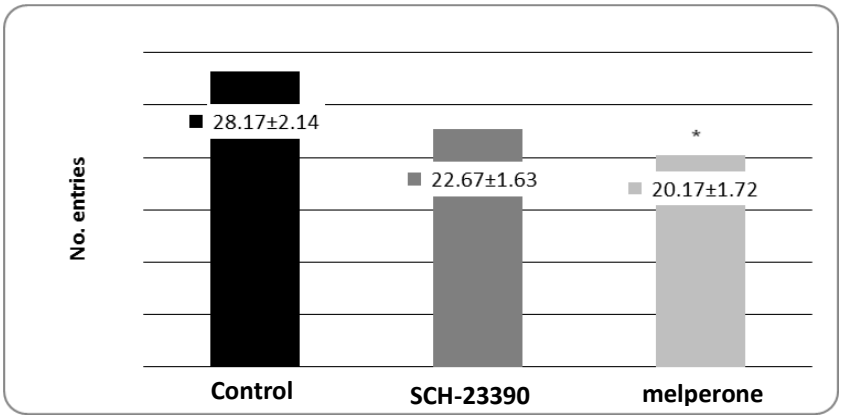

Fig. 2. Effects of SCH-23390 and melperone administration on the number of arm entries in Y-maze test. Values were expressed as mean ± S.E.M. of the number of arm entries. *p<0.05, **p<0.01 vs control

At the same time, only a tendency of reduced exploration capacity after the treatment with SCH 22390 in rats was noticed (tab. IV).

The treatment with melperone determined a statistically significant (p<0.05) diminution of the number of arm entries (mean ± S.E.M. number of arm entries was 20.17±1.72) compared to saline treated rats. These results suggested that melperone generated deficits of performance in Y-maze test (fig. 2) (tab. V, VI).

This nonspecific depressant behavioral effect observed in Y-maze test could be due to the inhibition of D2 dopaminergic receptor.

The administration of dopaminergic receptor antagonists induced a reduction of the same arm return and alternate arm return number, statistically significant ($p<0.05$) more intense in melperone group compared to controls (tab. VII).

No changes in latency of the first arm visit were found between groups treated with SCH-23390, melperone and saline solution.

TABLE VII

The effect of SCH-23390 and melperone in Y-maze test (same arm return, alternate arm return, latency first arm visit). Values were expressed as mean ± S.E.M. *p<0.05, **p<0.01 vs control.

	Number of same arm return	Number of alternate arm return	Latency first arm visit (seconds)
Control	6.3±1.17	4.2±1.23	22.64±1.73
SCH-23390	4.5±0.73	3.6±0.64	21.17±0.90
melperone	2.4±0.33	1.2±0.17	21.37±1.25

DISCUSSION

The present research established the inhibition of exploratory and locomotors activity of rats induced by consecutive 14 days administration of melperone and only a tendency for reduced exploratory activity following SCH 22390 administrations. This nonspecific depressant behavioral effect could be due to the inhibition of D2 dopaminergic receptor.

Previous reports have described a facilitation of rat spatial working memory determined by D1 receptor antagonist SCH 22390 administrations in the radial arm maze. In this behavioral experimental model SCH-23390 influenced short-time memory, without affecting long-time memory of experimented animals (12).

Different studies using a variety of approaches suggest that dopamine pathway may be a key element in modulating activity in the central areas to facilitate behavioral flexibility (13, 14, 15).

Various researches indicated that dopamine D1 and D2 receptors have been involved in recognition memory processing but their implications in different phases of this cognitive process remains uncertain.

The central dopamine receptors, especially D1 receptors in the prefrontal cortex, may be very important for mediating dopamine effects on cognitive functions (8).

It has been visibly established the involvement of dopamine receptors subtypes in the mediation of cognitive functions and in spontaneous exploratory behavior in rodents (13, 16).

The contribution of different central nervous system areas, particularly hippocampus, in spatial memory and exploration capacity of laboratory animals is well recognized (17).

Experimental studies illustrate that SCH 23390 may prevent the spatial working memory disturbances induced by active substances of marijuana, block of apomorphine-induced stereotypy and methamphetamine-induced lethality in experimental models (18). Also it presented antistereotypic effects, cataleptogenic effect and inhibitory effect on amphetamine circling in different laboratory animal species (3).

Dopaminergic receptors (D1, D2, D3, D4, D5), described in 1979 are G-protein coupled receptors that mediate the activity of the neurotransmitter dopamine, being involved in spontaneous behavior, reward, in pleasure and motivation, blood pressure control and hormonal secretion regulation (19).

D_1 receptors are found at high levels in the typical dopamine rich regions of brain such as the neostriatum, substantia nigra, nucleus accumbens and olfactory tubercle, whereas the distribution of the D_5 receptors is more restricted (20, 21, 22). D_1 receptor mediated important actions of dopamine to control movement, cognitive function and cardiovascular system activity. The functions of D_5 receptors are not very well known until now (23). D_1-like receptors show high affinity for SCH 23390 and SKF 83566 which are selective antagonists for these subtypes and also moderate affinities for typical dopamine agonists such as SKF 82958, SKF 38393, SKF82526 and dihydrexidine (21, 24).

D_2-like receptors show high affinity for selective antagonists such as: butyropenones (e.g. haloperidol) and the substituted benzamides (e.g. sulpiride), phenothiazines and thioxanthines (23). Most antagonists show a stronger affinity for the D_2 receptor (e.g. pimozid) compared with the D_3 and D_4 receptors. The D_2-like subtypes manifest moderate affinities for typical dopamine agonists with the D_3 receptor generally showing higher affinities for agonists than the other subtypes (25).

The D_2 receptor is the principal subtype in the brain and is found at higher levels in typical dopamine rich zones. D_3 and D_4 receptors are found at much lower levels and in a more restricted distribution, especially in limbic areas in the central nervous system (24, 26). The D_2 receptor mediates the effects of dopamine to control movement, some aspects of behavior in the brain and prolactin secretion from the anterior pituitary gland (23).

The functions of the D_3 and D_4 receptors are not clear, although their localization suggests roles in cognitive, affection and behavior function (27).

CONCLUSIONS

The present research indicates that 14 consecutive days administration of D2 dopaminergic receptor antagonist melperone is associated with the enhancement of cognitive functions in rats. This was proved to be more efficient in facilitating extinction learning. Moreover, the experiment revealed the inhibition of exploratory locomotor

activity induced by consecutive 14 days administration of melperone in rats.

The Y-maze test used to assess aspects of cognitive function and learning in rats showed an improvement of spatial memory in the rats exposed to D1 dopamine receptor antagonist SCH 23390 indicated by an increase of spontaneous alternation rate compared to controls, suggesting significant effects on short-term memory.

CANDIDA ALBICANS BIOFILM

Candida albicans is a major human fungal pathogen causing mucosal and deep tissue infections of which the majority is associated with biofilm formation on medical implants. Biofilms have a huge impact on public health, as fungal biofilms are highly resistant against most antimycotics. Animal models of biofilm formation are indispensable for improving our understanding of biofilm development inside the host, their antifungal resistance and their interaction with the host immune defence system. The study's authors have demonstrated for the first time that non-invasive, dynamic imaging and quantification of *in vitro* and *in vivo C. albicans* biofilm formation including morphogenesis from the yeast to hyphae state is feasible by using growth-phase dependent bioluminescent *C. albicans* strains in a subcutaneous catheter model in rodents. They have shown the defect in biofilm formation of a bioluminescent *bcr1* mutant strain. This approach has immediate applications for the screening and validation of antimycotics under *in vivo* conditions, for studying host–biofilm interactions in different transgenic mouse models and for testing the virulence of luminescent *C. albicans* mutants, hereby contributing to a better understanding of the pathogenesis of biofilm-associated yeast infections (Greetje Vande Velde,Sonˇa Kucharíková, Sanne Schrevens,Uwe Himmelreich and Patrick Van Dijck Towards non-invasive monitoring of pathogen–host interactions during *Candida albicans* biofilm formation using *in vivo* bioluminescence. *Cellular Microbiology*, 2014, 16(1): 115–130)

HOMEWORK PARTICULARITIES FOR SMALL SCHOOL CHILDREN (Abstract): The present study was centered on the particularities of the duration of preparing homework, taking breaks during homework preparation, and the way the breaks should take place for small school children. **Material and methods**: The study has been done on a sample of 235 small school children from Oradea, 114 boys and 121 girls, between the ages 7 and 10 years old, using an anonymous questioner, with 41 items, which investigates the lifestyle of the small school children. **Results and discussion**: The duration of homework preparation it is significantly more reduced for the school children in 1st grade in comparison with the ones in 3rd grade ($p<0.001$); for school children in 2nd grade compared to the ones in 3rd ($p<0.001$) and for school children in 3rd grade compared to the ones in 4th grade. A percentage of 93% of children prepare their homework after lunch. Half of the children from grades I-IV prepare their homework with no break. A very small number of children spend their homework break time in a healthy manner, while the rest prefer to play computer games (46.95%) or to watch television (46.08%). **Conclusions**: More than half of the schoolchildren need 1-2 hours at home to prepare their homework. Most of the school children prepare their homework after lunch, in an optimal interval of time. Half of the questioned children prepare their homework with no break. Those who are taking breaks prefer activities which get the children even more tired, therefore being non-hygienic methods of spending homework breaks. **Keywords:** SMALL SCHOOL CHILDREN, HOME, BREAKS, PREPARATION OF HOMEWORK

While establishing a schedule for the small school child some rules need to be followed: dosing the effort in proportion with possibilities, particularities and health of the growing and maturing organism; alternating harder activities with easier ones; rhythmical alternation of activity with rest, grading the work done (1, 2).

It is appreciated that the 24 hours of a day are split into three groups: professional time, necessary biological time and free time. The professional time encompasses school hours, the time necessary for preparing homework, and the time necessary to go and come back from school. The biological time includes sleep hours, the time necessary for meals and individual hygiene. The remaining difference is the free time (1, 3).

The preparation of homework needs to be done in the interval of maximum output, between 15:00-17:00 o'clock, and not randomly (2, 4, 5). It is recommended to start with the harder subjects. First the written

assignments need to be done, then the reading followed by learning. Switching from one subject to another is done only after completing the homework of the subject first started. Short 10 minute breaks need to be taken in between different subjects, without replacing the school related intellectual activity with similar occupations which strain the nervous system, such as watching television. For the small school children, the homework activity needs to be limited to 1-2 hours daily (6-9).

The present study has centered on the particularities of the duration of preparing homework, taking breaks during homework preparation, and the way the breaks should take place for small school children.

MATERIAL AND METHODS

A study has been done on a population sample of school children from I-IV grade, from an elementary school in Oradea, using an anonymous questioner with 41 items which investigates the lifestyle of small school children.

The group of the small school children studied includes 235 children, out of which 114 boys and 121 girls, with ages between 7-10 years old. There were no significant differences found on the frequency placement by age and sex for small school children, the group being homogenous, $p>0.05$, in terms of distribution of participants by age gender.

Processing and interpretation of data were done using modern methods of advanced medical statistics. The data were electronically filled using Microsoft Excel, 2001 program and interpreted using PASW 18 (*SPSS 18*) 2010. The threshold of statistical significance was established at $p<0.05$, with the exception of the cases where the correction Bonferonni was applied, and the level of threshold of significance is mentioned in the text. The following statistical tests have been applied: chi-squared test, Mann-Whitney test, Kruskal-Wallis test.

RESULTS AND DISCUSSION

1. Homework time (fig. 1)

More than half of the small school children (56.89% in 1st grade, 66.07% in 2nd grade, 62.9% in 3rd grade and 45.76% in 4th grade) need 1-2 hours for homework, according to the hygiene-sanitary norms for this age group of school children. There are some children who need more than 2 hours for homework preparation, 12.5% in 2nd grade, 27.41% in 3rd grade and 49.15% in 4th grade. None of the children needs more than 3 hours for homework preparation, and 39.65% out of the ones in 1st grade need less than one hour for homework.

We found a significant difference in the duration of homework preparation between the grades, $H(3)=65.59$, $p<0.001$. We further investigated this result and the threshold of statistical significance was established at 0.008, according to Bonferroni correction. The duration of homework preparation it is significantly more reduced for the school children in 1st grade in comparison with the ones in 3rd grade, $U=924.5$, $z=-5.23$, $p<0.001$, $\varepsilon = 0.48$, the difference between the two grades being of medium to big size, respectively in comparison with the school children in 4th grade, $U=528.5$, $z=-7.03$, $p<0.001$, $\varepsilon=0.64$, difference between the two grades being of a big size. The duration of homework preparation is significantly more reduced for school children in 2nd grade compared to the ones in 3rd grade, $U=1254$, $z=-3.05$, $p<0.008$, $\varepsilon=0.28$, the difference

between the two grades being of small to medium size, respectively compared to the school children in 4th grade, U=790, z=-5.41, p<0.001, ε=0.50, the difference between the two grades being of big size. The homework preparation time is significantly more reduced for school children in 3rd grade compared to the ones in 4th grade, U=1347, z=-2.82, p<0.008, ε=0.25, the difference between the two grades being of small size. The rest of the differences are of no significance.

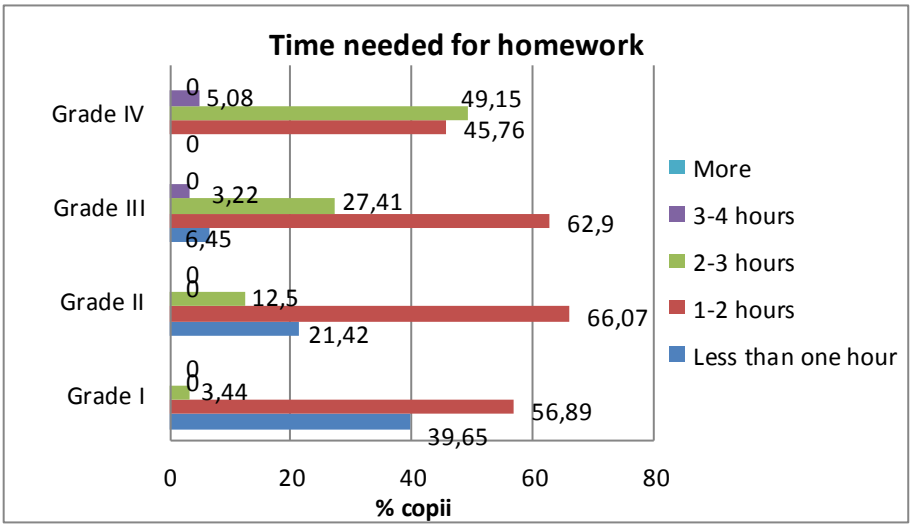

Fig. 1. Homework time for small school children

2. **The time of day when homework are prepared** (fig. 2)

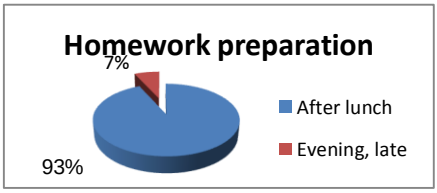

Fig. 2. Small school children homework preparation

The majority of children, a number of 219 (93%) prepare their homework after lunch, but there are 16 children (7%) who delay the preparation of homework for the evening time, entirely contraindicated, since the intellectual output is very low at the end of the day.

3. **The modality of homework preparation and using breaks** (fig. 3,4)

Half of the total of children from grades I-IV prepare their homework with no break, and more specifically 62.06% of 1st graders, 53.57% of the 2nd graders, 51.61% of 3rd graders, and 37.28% of the 4th graders take brakes during homework, 30 children (48.38%) of 3rd graders, 26 children (46.42%) of 2nd graders, and only 22 children (37.93%) of 1st graders.

Nevertheless, the differences in the modality of homework preparation between grades are not significant, p>0.05.

A very small number of children (2 in

2nd grade, 4 in 3rd grade, and 2 in 4th grade) spend their homework break time in a healthy manner, while the rest prefer to play computer games, 46.95% of the children's total, or to watch television, 46.08% of the children's total.

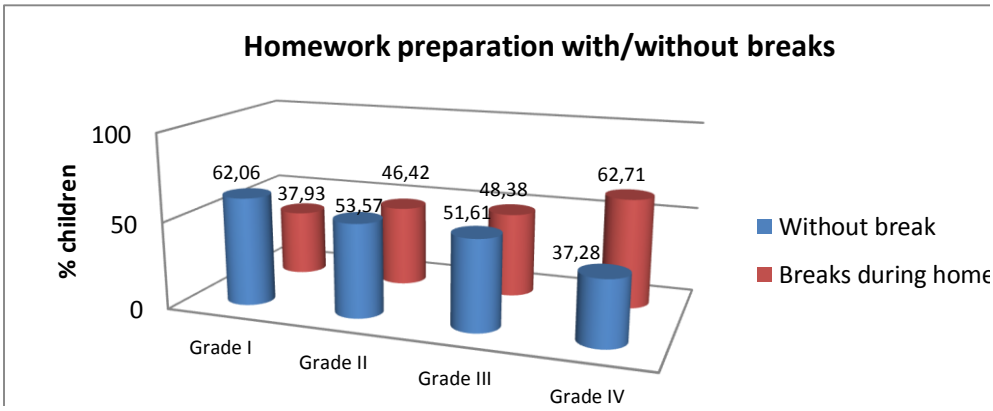

Fig. 3. The modality of homework preparation for small school children

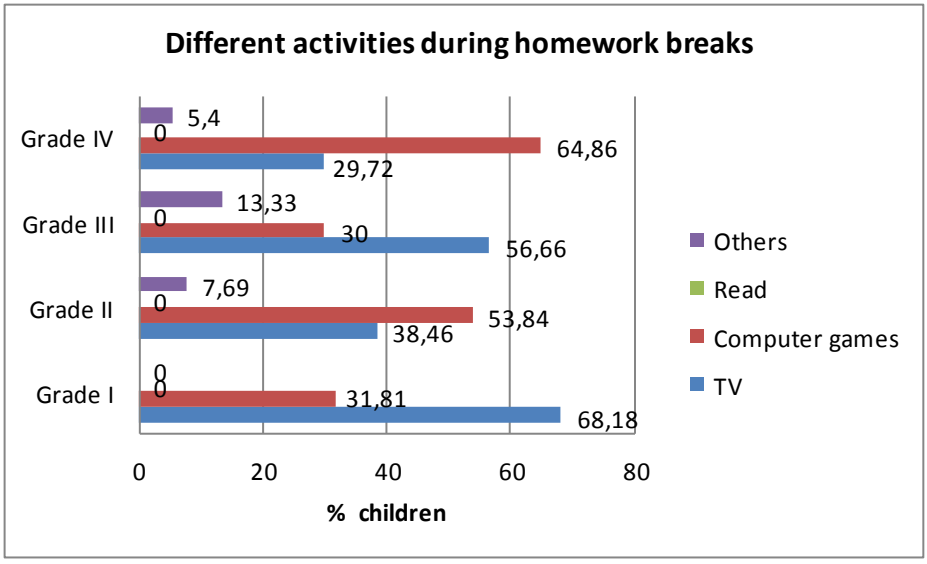

Fig. 4. Small school children use of breaks during homework

Both activities do nothing but get the children even more tired, therefore being non-hygienic methods of spending homework breaks.

CONCLUSIONS

More than half of the studied small school children from Oradea need 1-2 hours to prepare their homework, and are within the hygienic recommendations for this group age. The length of the homework preparation is significantly more reduced at the school children as the grade of study is lower.

A percentage of 93% of the school children prepare their homework after lunch during the optimum interval.

Half of the total school children from grades I-IV prepare their homework without breaks. Out of the ones who take breaks, half prefer to play computer games or to watch television.

ANTIDERMATOPHYTIC ACTIVITY OF *OTACANTHUS AZUREUS* ESSENTIAL OIL

In a study by Houël *et al*., the antidermatophytic activity of *Otacanthus azureus* (Linden) Ronse essential oil (EO) was tested alone and in combination with azole antifungals. The oil was extracted from aerial parts of the plant and its chemical composition was analyzed by gas chromatography/mass spectrometry. In vitro antifungal activity was evaluated by broth microdilution techniques and minimum inhibitory concentrations as low as 4µg ml^{-1} were obtained. The combined effect of *O. azureus* EO with azoles (ketoconazole, fluconazole, itraconazole) was analyzed using chequerboard assays, showing synergism against *Trichophyton mentagrophytes*. Also, cytotoxicity of O. *azureus* essential oil to VERO cells was low. In conclusion, the study highlights that *O. azureus* essential oil represents a promising antifungal agent for treatment of dermatomycoses (Houël E, Rodrigues AM, Jahn-Oyac AD et al. In vitro antidermatophytic activity of Otacanthus azureus (Linden) Ronse essential oil alone and in combination with azoles. *J Appl Microbiol*. 2013. doi: 10.1111/jam.12377).

ETHICAL EVALUATION MODEL FOR TECHNOLOGIES. THE ROLE OF MEDICAL TECHNOLOGY IN THE DEVELOPMENT OF AUTONOMY IN DIABETES PATIENT

Simona Damian, Roxana Necula, A. Sandu, Maria Liliana Iliescu, Beatrice Ioan

Center for Ethics and Health Policy

ETHICAL TECHNOLOGY ASSESSMENT MODEL. ROLE OF HYEALTH TECHNOLOGY IN THE DEVELOPMENT OF AUTONOMY IN DIABETIC PATIENT **(**Abstract**):** Romanian Government Decision (GD) No. 8/2012 amending and supplementing GD No. 144/2010 regarding the function and organization structures of the Ministry of Health defines health technology assessment (HTA) as "a systematic and multidisciplinary analysis of the existing and new medical technologies, through which medical, economic, social, ethical and organizational information are synthesized so that medical technologies to be used in a transparent and unbiased manner". We propose an ethical assessment model of technologies used in the care of diabetic patients. The nature of this research was exploratory, giving the novelty of this approach to the clinical and social context of Romania. Material and Methods: The assessment of health technologies used in the care of diabetic patients was based on the following research question: What is the role of health technology in developing autonomy and responsibility in patients suffering from chronic diseases? Individual interviews and focus groups were held from June, 2011 to November, 2012 in Iasi. The criterion for selecting the participants was belonging to the target groups: family doctors or diabetes specialist, patients with type 1 (T1D) and type 2 diabetes (T2D), caregivers and other professionals involved in diabetes patient care. Results and conclusions: The diabetic patient benefits from a specific treatment and has the privilege of self-administering it, his life expectancy and quality of life depending upon the compliance and responsibility he demonstrates. **Keywords:** ETHIC EVALUATION, TECHNOLOGIES, AUTONOMY, DIABETES PATIENTS

Health Technologies (HT) are variously defined. One approach is based on interventions and defines HT as a wide range of products used to diagnose, monitor or treat a disease or medical condition, aimed at improving the quality of healthcare provided to patients with an early diagnosis, less invasive treatment options, and shorter hospital stay and recovery time (1,2). Another definition is focused on structure, HT being understood as "medical services, drugs, medical or surgical instruments and techniques used in health care as well as the organization and support care system provided" (2,3). Health technology assessment (HTA) is necessary for both economic and ethical reasons, HTA meaning "a comprehensive strategic research form (Policy Research) which explores the direct and indirect consequences, intended and unintended, short-and long-term technology applica-

tions, or a systematic evaluation of properties, effects and/or other impacts of technologies in health care" (2,3).

National legal framework regarding health technology assessment

Romanian Government Decision (GD) no. 8/2012 amending and supplementing GD no. 144/2010 regarding the organization and function of the Ministry of Health defines health technology assessment as "the systematic and multidisciplinary analysis of the existing and new medical technologies, through which the medical, economic, social, and ethical information on the use of health technologies are synthesized in a transparent and unbiased and manner " (GD 8/2012). The lawmaker believes that "the purpose of health technology assessment is to provide information support for the formulation of an effective, safe, patient-centred health policy and making decisions that ensure obtaining the greatest possible added value" (GD 8/2012). We draw attention on the approach specific to utilitarian ethics used by the lawmaker in HTA. This assessment is applicable to drugs, medical devices, equipment and advanced medical techniques, health policies, medical services and procedures, organization and management of health systems, including those covered by national health programs (GD 8/2012).

In Romania, the institutional HTA agency is the Ministry of Health which is the competent national authority in this field (GD 8/2012).

The principlism approach of ethical assessment of health technologies

Principlism was first formalized in a document called the Belmont report and the four bioethical principles proposed by Beauchamp and Childress. These four principles in the interpretation of Ion Mureşan (4) are:

1) autonomy: respecting the ability of autonomous individuals to make decisions, giving them the freedom to make choices regarding their life according to their conscience;

2) beneficence: requires weighing the benefits against costs and risks - including the duty of aiding others to promote their interests;

3) nonmaleficence: human subjects should not be harmed, the actions causing more harm than benefits being avoided;

4) justice: consists in a group of norms for fairly distributing benefits, risks and costs - fairly distributed medical goods and services (4,5).

Ion Mureşan shows that the four principles of Beauchamp and Childress are therefore the core of what the authors call "common morality", meaning fundamental moral norms shared by all morally serious persons in all places. Therefore this procedure was called "the four principle bioethical approach" or "principlism" (4).

The assessment proposed in the present research exclusively considers the autonomy principle and the role of health technologies in the development of autonomy and responsibility of chronic patient for his health. For Beauchamp and Childress (5) autonomy is self-empowerment outside the control and intervention of others which generates a meaningful choice. Autonomous, sovereign individuals are free to act according to their own plan (6). The two authors believe that the respect for the autonomy of patients and their healthcare-related choices is one of the four fundamental principles of bioethics (5).

Assessed health technologies

Of the definition of health technology in the Romanian law (GD no. 8/2012 amending and supplementing GD no. 144/2010 regarding the organization and functioning of the Ministry of Health) for the present study we selected the following:

a. drugs: insulin for insulin-dependent diabetic patients and antidiabetics for non-insulin-dependent diabetic patients;

b. medical devices: self-monitoring blood glucose devices, glucometers;

c. equipments and advanced medical techniques: insulin pumps;

d. health policies, medical services and procedures, organization and management of health systems, including those covered by national health programs (GD 8/2012), in this case - the National Diabetes Program.

The primary focus was the ethical parameters in close connection with the related social issues.

MATERIAL AND METHODS

The assumed paradigm of social-constructionist research is that social reality is a product of negotiation between the interpretations of social actors. The research consisted in phenomenological analysis and symbolic interactions based on the study paradigm (2).

The nature of this research was exploratory given the novelty of this approach to the Romanian clinical and social context. The ethical assessment of medical technologies used in the care of diabetes patients relied on the following question: What is the role of medical technologies in developing the autonomy and responsibility of chronic patients? Individual interviews and focus groups were held in Iasi from June, 2011 to November, 2012. The criterion for selecting the participants was that of belonging to the target groups: family doctors or diabetes specialist, patients with type 1 (T1D) and type 2 diabetes (T2D), caregivers and other professionals involved in diabetes patient care (2). Both female and male individuals were selected. Participants were selected with support from Iasi Diabetes Clinic and Family Doctors Association, and invitation directly sent by the organizers to the focus group. Snowball sampling was taken into account: the interviewed suggested interviewing other significant people (2). Interviewed persons were allowed to fully express their ideas without exceeding the thematic focus until they finished what they had to say. Each interview lasted 40-50 minutes, being recorded with the consent of the interviewees, and then transcribed. Research was conducted in compliance with the principles of proper conduct in scientific research (Romanian Law 206/2004), in agreement with national and international research ethics documents.

Validity: Given the generative exploratory nature of this research, sampling had not in view the validity criteria specific to a quantitative study, but the completeness of quantitative information generated by saturating the sample. The sample was considered saturated when no responses appeared significantly different in the new interviewed subjects. The research consisted in a case study conducted in the Iasi County**,** where the only diabetes clinic in Moldova (the Eastern region of Romania) is located (2). Data validity is limited to the specific discursive universe of diabetes specialists, family doctors and diabetes patients in Iasi County, but with at least a nationwide extrapolation potential given the similarities in diabetes clinical practice.

RESULTS

Health behaviour is recognized, articulated and formalized into a major problem for public healthcare programs (2). The new meaning of the term is related to the description of autonomous individuals who can choose whether to act in response to a disease or to maintain health (2). Individual behaviours were analyzed with a less deterministic grid, emphasizing the capacity of individuals to act (7, 8), make choices, and be autonomous in health-related matters (9, 10).

In the last two decades the new approach to health behaviour depicts the patient as a person making autonomous choices about how to act or not to act in relation to his health (2). The approach evolved conceptually from the autonomy seen as central value by Kant, through Mill's interpretation of autonomy as instrumental value to the modern theories on autonomy as authenticity, relational autonomy, informed consent, etc. (6).

A. Insulin and antidiabetic agents

Because chronic diseases require continuing medical care, they may raise the issue of care strategies effectiveness and of the balance doctor/patient involvement in the therapeutic process (12, 13). The participation of professionals and patients in the care process requires the patients to assume responsibility (14, 15), and care providers to provide information and autonomy support, as well as a collaborative process for optimizing long-term outcome (2, 16).

"*First of all, when your glucose level was good all day, do you feel good because you succeeded, you could, you ate, you injected insulin, made exercise, and did everything right? You feel good on the inside, not necessarily ... This and that helped you a lot, I will try to do the same tomorrow, if I was able do it today why shouldn't I do it again tomorrow ? And so, this motivates you the next day to succeed in achieving a good blood sugar level." (Diabetes patient)*

Respondents highlighted the improvements in insulin therapy over the last years.

"During Ceausescu's regime, when injection tools were rudimentary, insulin was injected using glass syringes and Chinese needles that got calcium, tartar and needed to be boiled daily. I had to learn because I was explained that otherwise I could die. (...) The only complaint might be related to a specific punctuality (needed) for insulin injections. Sort of constraint." (Diabetes patient)

Overcoming many drawbacks related to how to self-administer insulin and eliminate its constraints was mentioned as a progress in insulin therapy. In terms of principlism ethics, we are talking about a deeper beneficence of this therapeutic form. In the absence of insulin type 1 diabetics may die relatively shortly, thus therapeutic compliance is mandatory. The degree of inherent discomfort is minimized by eliminating the need for a tools kit. Instead of glass syringes with metal needles that had to be sterilized, disposable needles are used.

"I never perceived it as a constraint, but unlike now, but there was a very large bag of tools; carrying a pot and syringes was not exactly comfortable nor enjoyable and people who didn't have medical information or medical culture looked somewhat strangely at you. It is true that not many people knew that I was a diabetic because the impact on a stranger could get me upset, and spoil my or his mood, too. I often avoided these things." (Diabetes patient)

The ease of today self-treatment and self-monitoring allows the diabetic patient a level of privacy in his social environment.

This approach of individual health behaviours, which emphasizes the social agent skills, has such benefits as reducing costs and decreasing the pressure on the healthcare system, empowering individuals and improving their health, but raises other problems. Increased responsibility for self-care assumed by patients raise specific challenges for those with multiple problems, such as worsening of a problem by treating others (2, 11).

Patients with chronic disease face a range of needs which change their lifestyle and usually lead to behaviours that promote physical and psychological wellbeing, which requires them to modulate their relationship with healthcare providers and to adhere to medical treatment, to monitor their health condition, to make care-related decisions, to manage the impact of the disease on their physical, mental and social functioning (2, 11).

B. Glucometer: self-monitoring and self-management of care

The interviewed physicians emphasized that self-monitoring devices are accessible and provided free of charge.

"You'd rather concentrate on self-monitoring devices, glucometers and test strips, nowadays prescribed free of charge to all insulin-dependent patients, which automatically is a big step forward compared to the years when I started residency, the patients having to make a financial effort. Maybe that is more relevant, I do not know" (Diabetes doctor).

From an ethical standpoint, free of charge self-monitoring devices are an implementation of the principles of beneficence and equity.

"(Regarding) technologies, if you want to know what is really relevant for the diabetic population, in my opinion the daily self-monitoring devices rank first. I think these are the most representative for the ordinary diabetes patient." (Diabetes doctor)

Relevant technologies are viewed in terms of accessibility to patients with median income, in terms of their capability to produce maximum improvement in as many patients. A technology is assessed by doctors according not only to its intrinsic medical value, but from an ethical and social perspective, that is from the perspective of beneficence and utility.

"They should be used with maximum efficiency. (....). Patients go home and eventually the tests expire and they do not use them. A patient came to me with a blood sugar meter and I saw he used it only three times in the last three months. So many test strips payed by the government are wasted; it is a waste of money on people who did not understand well what they got or they go and offer tests to their grandmother, friends, neighbour, priest in his village, and to the teachers and ... who knows who else, or they sell them." (Diabetes doctor)

Doctors discussed how technology is used by patients, insisting on the fact that the importance of this tool in diabetes self-management is not understood. This leads to waste of resources and, in the opinion of respondents, to unfair, unequal allocation.

"I have few diligent patients; they keep a daily record of their blood glucose levels. ... The normal blood glucose level is 100 (mg/dl), but they have 350, 400, 420, day after day, but never once went to ask

the doctor: "Look, my blood glucose is more than 4 times greater". Why do we give these people tests?" (Diabetes doctor).

Physicians underlined the importance of patient responsibility for his health condition focusing on the usefulness of free of charge prescription of blood glucose measuring devices in circumstances of misuse by the patient. They also believe that the use of glucometer, even if daily, is not enough. Knowledge on insulin dose adaptation to blood glucose level is also required; a diabetic patient unable to do that has to ask for medical help.

Also, diabetes patients understand the importance of self-management, taking control of their long term conditions and lifestyle.

"The doctor told me to do this test before I eat certain foods I know to cause an increase in blood glucose level and to see what happens. For example, boiled potatoes, for sure a potato dish will increase my blood sugar no matter how I cook it. She told me to check my blood sugar before I eat potatoes; first eat two potatoes and check for an increase (in blood glucose level), than eat one potato and also check for an increase. Well, I don't have the patience to do that"(Diabetes patient).

One of the interviewed physicians focused on patient opportunity to take control of their care process through frequent blood glucose measurements. This increases the degree of patient autonomy, giving him the chance to make informed decisions, and take responsibility for the decisions he makes.

"It is a minister's order and it says: one hundred tests; if it were my decision if a patient is disciplined, he deserves more tests, maybe 150 or 200; if the patient is not disciplined, I would give him only one box - 50 tests or I would give him nothing at al." (Diabetes doctor).

Inequity occurs between T1 diabetes patients - receiving free of charge blood test for blood glucose, and T2 diabetes patients who do not receive the same kind of gratuity. Inequity is also seen in patients suffering from other diseases not included in national programs.

"There are cases in which T2 diabetes patients who do not take insulin do tests more often than those with T1 diabetes (...) Inequity with other diseases, here there are so many things free of charge and the benefit for some patients is questionable. But heart failure is also a disease, and cirrhosis is a disease and nothing is free of charge in their treatment" (Diabetes doctor.

C. Insulin pump. Medical technology and responsibility for health

Insulin pump is considered cost-prohibitive by interviewed doctors, so they do not consider it relevant for assessing the ethics of technology used in diabetic care.

"If a diabetic comes up with the idea that he wants a pump. Let's see if the pump suits you. Insulin pump is not a device that replaces the pancreas and determines the insulin dose according to blood sugar level. I eat as much as I want and the pump does the job. No. And this device requires sometimes pressing a button, some adjustments. Thus, sometimes it's maybe harder to use a pump than having some already fixed doses of insulin" (Diabetes doctor).

The interviewed physicians considered that the difficulties the diabetes patients are faced with in order to follow an appropriate lifestyle in precarious financial conditions as a main public health problem; in this context of pauperism, technologies, even

the very advanced ones, if available at high costs, are irrelevant for care management and more, they can lead to a number of access-related inequities.

"I do not know if insulin pump is the best example of technology due to the fact that insulin pump is a very expensive device, and automatically prohibitive for most patients" (Diabetes doctor).

D. The National Diabetes Program

Diabetes was identified as the main cause of worsening the problems generated by chronic diseases. WHO statistics allow an estimation of the problem in Romania (2). Thus, in recent years there has been a marked increase in the prevalence of diabetes in Romania, with an almost 5-fold increase compared to the number of cases recorded during the two decades interval 1989 to 2009 (WHO/Europe, European HFA Database, data known to July 2010). Since 2006, Romania has a national diabetes program (Source: Diabetes - The Policy Puzzle, Country overview, Romania, 2008), technically coordinated by the "N.C. Paulescu" National Institute of Diabetes, Nutrition and Metabolic Diseases (2). This Institute coordinates the annual monitoring and prevention of diabetes complications, self-monitoring of diabetes patients, access to specific treatments, including insulin pump; the Institute is also the administrator of the National Diabetes Register.

"... let's take a bad example related to technologies: the patient may not realize, as in many other situations, that if something is given free of charge it does not mean that there is no financial effort behind what is offered to him, and I think this a problem with many of our patients. Maybe, sometimes we cannot explain quite clearly, maybe we cannot make ourselves understood, however that stuff costs something, but there is a degree of indifference to what is given free of charge." (Diabetes Doctor)

From an ethical standpoint, the National Diabetes Program is tributary to the utilitarian model of care.

"...creates a new type of addiction, because the diabetic patient becomes addicted to a right he does not use properly, as intended, and cannot be monitored outside medical units. What is he doing, how much is he really doing." (Diabetes doctor)

Respondents pointed out the risk of creating a relation of dependency on healthcare system instead of mobilizing patient's resources to increase self-care management.

National Diabetes Program is considered absolutely necessary for patients, in the absence of free insulin their life being threatened. This Program also compensates patients' socio-economic vulnerabilities.

"Let's hope it will not undergo changes …otherwise… it would be a great misfortune, at least for those (patients) with type 1 diabetes, it will be disastrous if test will not be prescribed free of charge because only few have the financial means to buy their own tests." (Diabetes doctor)

The components of the National Diabetes Program are prevention and control of diabetes, insulin and oral hypoglycaemic agents being provided free of charge. According to the program, family doctors are responsible for the care of noninsulin-dependent diabetics, and diabetes doctors for the insulin-dependent patients. A check-up with the diabetes doctor is required every three months for each diabetes patient, being carried out in the county diabetes centres.

The interviewed doctors emphasized

how important is the patients to be aware of the value of health technology and of the costs of freely provided devices and consumables through the National Diabetes Program.

Beside its medical objective, as underlined by diabetic patients, the National Diabetes Program also has a social dimension.

"At the end of the month, when all my pension money are spent and I have no more tests I go to the inpatient diabetes clinic ... because I have no more money to buy food. Do you believe me? It happened to me last month, and they also did blood glucose tests. I go there to get artificial feeding (intravenous glucose administration) because I have no money for food and if I do not eat I get into ketosis. I can live without food, but last month I lost very much weight, but now I am somewhat better. I have to eat at least once a day, they give me glucose and buffered insulin to avoid other complications, this doesn't seem normal to me." (Diabetes patient)

CONCLUSION

Our findings show that people with chronic illnesses develop autonomy through various relationships in the unique context of their life, social interactions, including mutual reactions of thoughts, feelings, concerns and habits, autonomy being negotiated during daily activities both in professional and family relationships (17).

As shown in the literature, the factors influencing patient autonomy are: health status/associated diseases (co morbidity); treatment; knowledge (about their disease); experience and skills; the personal way of approaching the disease; family patterns; type of relationships with others; history/life experience; social context (2,17). Self-management in diabetes (and other chronic diseases) relies more heavily on medical technology to monitor behaviour and/or biomedical parameters. These technologies are part of the psychosocial aspect of daily life (18).

Our study also shows that the patients suffering from diabetes mellitus have a high degree of autonomy given the type of treatment they receive and the possibility of disease self-management.

CONTROLLED OVARIAN HYPERSTIMULATION AND IVF PREGNANCY PROGNOSIS

Andreea Enache*, B. Marinescu*, T. Enache*
"Prof. Dr. Panait Sîrbu" Clinical Hospital of Obstetrics and Gynecology, Bucharest

CONTROLLED OVARIAN HYPERSTIMULATION AND IVF PREGNANCY PROGNOSIS (Abstract): IVF (*in vitro* fertilization) often represents the ultimate step in our attempt to treat infertility. Nowadays this method is more and more used, couple's expectations are higher and higher, so that optimizing the chance that one IVF pregnancy became a healthy newborn child is becoming an important issue. In this study we analyzed the controlled ovarian hyperstimulation impact on IVF pregnancy prognosis. We studied 307 patients who had IVF fresh procedures in "Panait Sîrbu" Clinical Hospital of Obstetrics and Gynecology - Department of Assisted Human Reproduction between 01.01.2008 – 31.12.2010 and obtained pregnancy; pregnancy rate according to our statistics is 34%. For statistic analysis we used the odd Student test. Our data proved better results (defined as a better birth/ abortion ratio) for the patients where recombinant FSH was used towards patients where highly purified urinary gonadotropin or the combination of the two drugs was used. Our statistical data also proved that none of the variables: age, BMI (body mass index), endometrium thickness, number of oocytes, number of embryos or number of days of stimulation is a favorable variable for this better result, but the number of units of gonadotropin is a favorable variable for a better birth/ abortion ratio. We consider that our data gives an interesting perspective upon the connection between controlled ovarian hyperstimulation and pregnancy outcome, especially these days when tendencies are to obtain as many oocytes in one procedure as we can, which often means to use high doses of gonadotropin. **Keywords:** *IN VITRO* FERTILIZATION, CONTROLLED OVARIAN HYPER STIMULATION, PREGNANCY, PROGNOSIS.

Nearly 13-15% of reproductive aged couples are infertile (1). Infertility is a real health problem; it is always associated with emotional stress and affects couple's social life and work. This means a long term impact on society because it affects family stability on one hand, and on the other hand treatment is often expensive and consumptive.

In vitro fertilization (IVF) often represents the ultimate step in our attempt to treat infertility. Nowadays this method is more and more used; couple's expectations are higher and higher, so that optimizing the chance that one IVF pregnancy became a healthy newborn child is becoming an important issue (2, 3). One of the most important adverse outcomes attributed to IVF pregnancy is a high incidence of spontaneous abortion rate: 25 – 35% (4, 5).

In our attempt to understand and minimize the IVF pregnancy spontaneous abortion rate we analyzed the qualitative and quantitative impact of controlled ovarian hyper stimulation during IVF procedures

on pregnancy outcome, defined as the birth/ abortion ratio.

MATERIAL AND METHODS

We studied 307 patients who had IVF fresh procedures in "Panait Sîrbu" Clinical Hospital of Obstetrics and Gynecology, Bucharest - Department of Assisted Human Reproduction between 01.01.2008 – 31.12.2010 and obtained pregnancy; pregnancy rate according to our statistics is 34%. Patients were divided in 3 major groups according to the medication used for controlled ovarian hyperstimulation (recombinant follicle-stimulating hormone (FSH), highly purified urinary gonadotropin and the combination of the two drugs) and we analyzed the birth/ abortion rate for all the 3 groups and the impact on the result obtained of a few variables: age, body mass index (BMI), endometrium thickness, number of oocytes retrieved, number of embryos obtained, number of days of stimulation and number of units of gonadotropin used for ovarian hyperstimulation per day. All patients had normal basal FSH and normal antral follicular count. All patients had long or short protocols for ovarian hyperstimulation. For statistic analysis we used the odd Student Test.

RESULTS

From the 307 patients who obtained pregnancy by IVF fresh procedures, 226 patients gave birth to one or more newborns (73.6%) and 81 patients suffered an abortion in the first or second trimester (26.4%) (fig. 1).

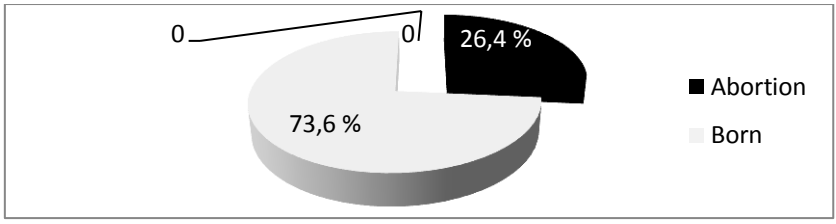

Fig. 1. Pregnancy outcome after IVF fresh procedures

Our first intention was to see if there is any difference between the group of patients whose pregnancies ended with birth and the group of patients whose pregnancies ended with abortion.

Student Test for patients' age, for the patients whose pregnancies ended with birth (group A) towards those whose pregnancies ended with abortion (group B) is presented below (fig. 2.).

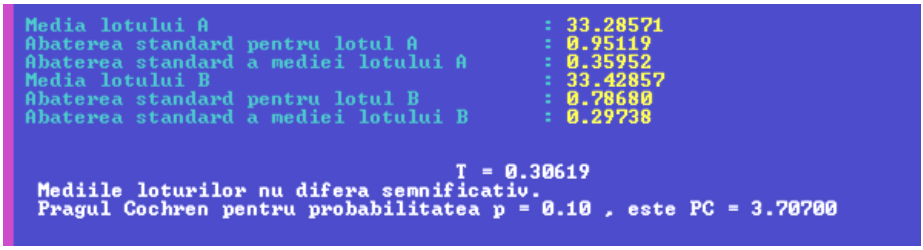

Fig. 2. Student Test for patients' age for patients who obtained pregnancies after IVF fresh procedures.

Average age for the patients who's pregnancies ended with birth (group A = 33.3 years) is not statistically different from average age for the patients who's pregnancies ended with abortion in the first or second trimester (group B = 33.4 years); p > 0.1 and T = 0.31.

Student Test for BMI, for the patients whose pregnancies ended with birth (group A) towards those whose pregnancies ended with abortion (group B) is presented below (fig. 3).

Fig. 3. Student Test for patients' BMI for patients who obtained pregnancies after IVF fresh procedures.

Average BMI for the patients who's pregnancies ended with birth (group A = 22.14 kg/m^2) is not statistically different from average BMI for the patients who's pregnancies ended with abortion in the first or second trimester (group B = 22.7 kg/m^2); p > 0.1 and T = 1.29.

Student Test for endometrium thickness, for the patients who's pregnancies ended with birth (group A) towards those who's pregnancies ended with abortion (group B) is presented below (fig. 4).

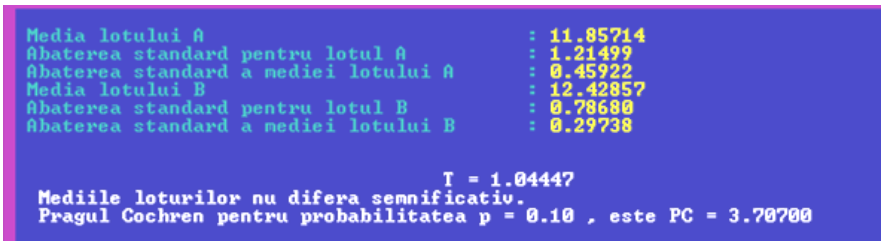

Fig. 4. Student Test for endometrium thickness for patients who obtained pregnancies after IVF fresh procedures.

Average endometrium thickness for the patients who's pregnancies ended with birth (group A = 11.8 mm) is not statistically different from average endometrium thickness for the patients who's pregnancies ended with abortion in the first or second trimester (group B = 12.43); p > 0.1 and T = 1.04.

Student Test for the number of international units (IU) of gonadotropin used per day for ovarian hyperstimulation, for the patients who's pregnancies ended with birth (group A) towards those who's pregnancies ended with abortion (group B) is presented below (fig. 5).

Average number of units of gonadotropin used for ovarian hyperstimulation for the patients who's pregnancies ended with birth (group A = 183.5 IU) is not statistically different from average number of units of gonadotropin used for the patients

who's pregnancies ended with abortion in the first or second trimester (group B = 201.0); p > 0.1 and T = 0.79.

Student Test for the number of days of hyperstimulation for the patients who's pregnancies ended with birth (group A) towards those who's pregnancies ended with abortion (group B) is presented below (fig. 6).

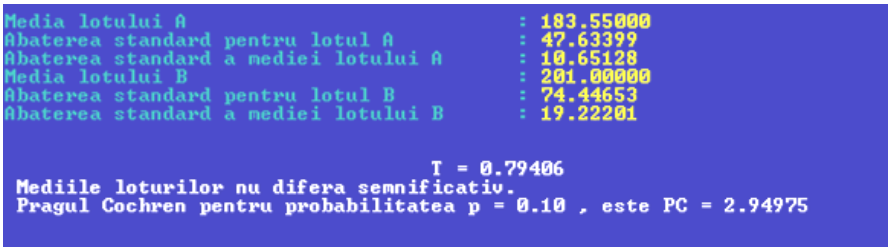

Fig. 5. Student Test for number of units of gonadotropin used for ovarian hyperstimulation for patients who obtained pregnancies after IVF fresh procedures.

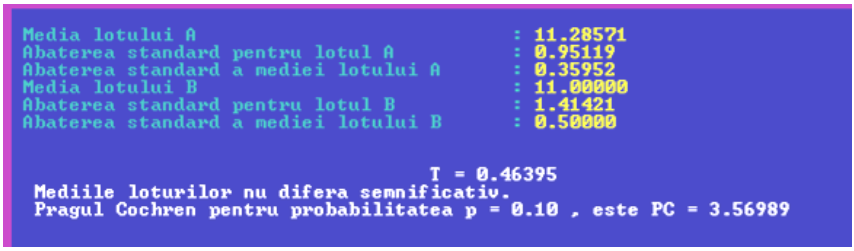

Fig. 6. Student Test for number of days of ovarian hyperstimulation for patients who obtained pregnancies after IVF fresh procedures.

Average number days of ovarian hyperstimulation for the patients who's pregnancies ended with birth (group A = 11.3 days) is not statistically different from average number of days of ovarian hyperstimulation used for the patients who's pregnancies ended with abortion in the first or second trimester (group B = 11.0 days); p > 0.1 and T = 0.46.

Student Test for the number of oocytes obtained from the patients who's pregnancies ended with birth (group A) towards those who's pregnancies ended with abortion (group B) is presented below (fig. 7).

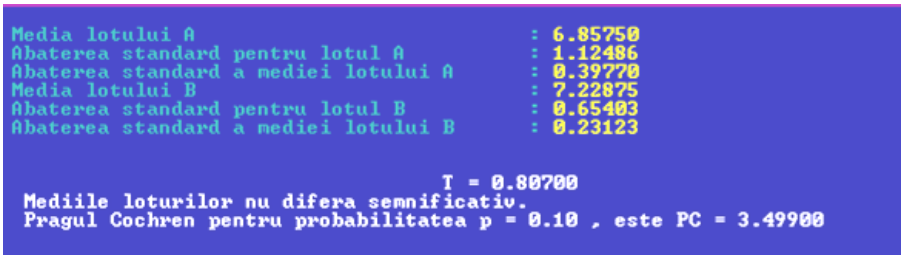

Fig. 7. Student Test for number of oocytes retrieved from patients who obtained pregnancies after IVF fresh procedures.

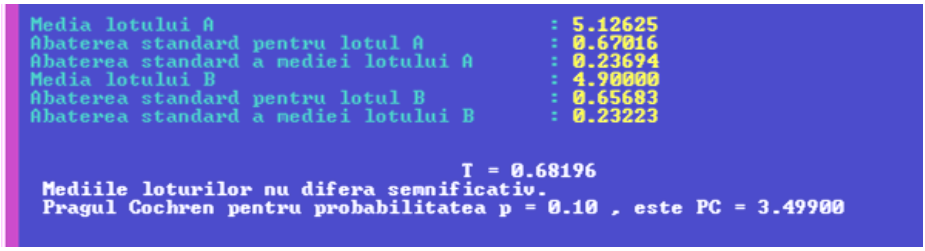

Fig. 8. Student Test for the number of embryos from patients who obtained pregnancies after IVF fresh procedures.

Average number of embryos from the patients whose pregnancies ended with birth (group A = 5.13) is not statistically different from average number of embryos obtained from the patients who's pregnancies ended with abortion in the first or second trimester (group B = 4.9); $p > 0.1$ and $T = 0.68$.

Student Test for the common variables of the two groups (age, BMI, endometrium thickness, number of oocytes retrieved, number of embryos obtained, number of days of stimulation and number of international units of gonadotropin used per day) demonstrated that the average values of these variables are not significantly different.

Our next step was to divide the 307 group of patients according to the medication used for controlled ovarian hyperstimulation: 157 (51.1%) patients received recombinant FSH – group A, 42 (13.7%) patients received recombinant FSH and highly purified human gonadotropin – group B, 106 (34.5%) patients received highly purified human gonadotropin – group C, in 2 (0.7%) patients natural cycle was used – group D and in 1 (0.33%) patient we used a combination of clomiphene, highly purified human gonadotropin and recombinant FSH – E. (fig. 9).

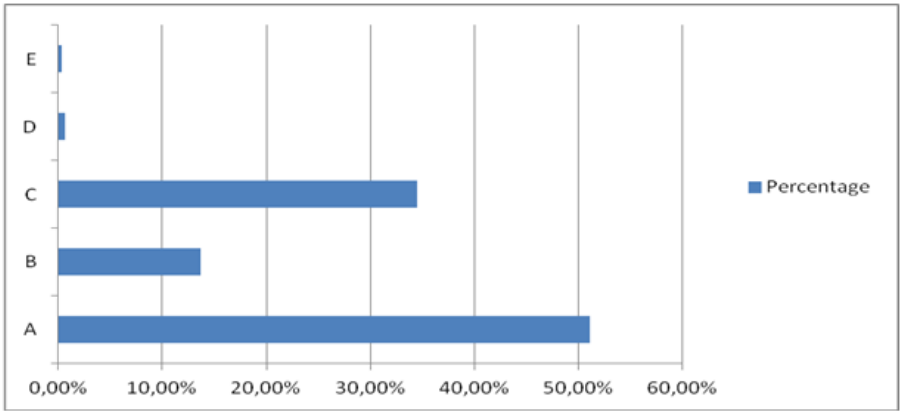

Fig. 9. Patients' distribution according to the medication used for ovarian hyperstimulation

We analyzed only the three groups of patients where the number of patients was good enough for the statistics (A, B and C). We calculated for each group the birth/abortion ratio and we considered the best ratio as the best pregnancy outcome.

For the group of patients who received recombinant FSH for ovarian hyperstimulation the birth/ abortion rate was 3.24 (FSH group). For the group of patients who received highly purified human gonadotropin for ovarian hyperstimulation the birth/ abortion rate was 2.31 (HPHG group) and for the group of patients who received both medications the birth/ abortion rate was 2.73 (FSH + HPHG group). These data point out that the best ratio (3.24) was for the group of patients where recombinant FSH was used, followed by FSH + HPHG group (2.73), the worst result being registered for the HPHG group (2.31) (fig. 10).

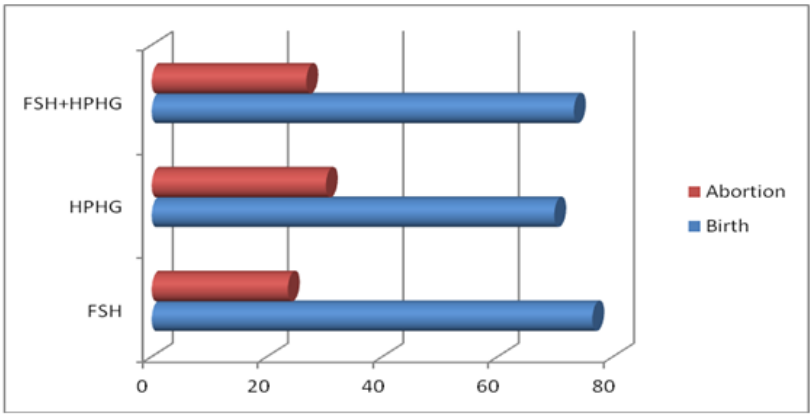

Fig. 10. Percentage distribution of pregnancies (birth and abortion) according to the medication used for ovarian hyperstimulation

The next step was to determine if there is any favorable variable for this result. We used the odd Student Test to calculate the average value for all the variables considered (age, BMI, endometrium thickness, number of oocytes retrieved, number of embryos obtained, number of days of stimulation and number of units of gonadotropin used per day) for all the 3 groups of patients (FSH, HPHG and FSH+HPHG) (tab. I).

TABLE I

Mean variables values according to the medication used for ovarian hyperstimulation

Variable	Unit of measure	FSH	HPHG	FSH + HPHG
Age	Years	33.39	33.78	34.19
BMI	kg/ m^2	22.48	22.72	22.22
Endometrium thickness	mm	11.98	12.01	11.8
Number of oocytes retrieved	-	7.3	6.56	7.05
Number of days of stimulation	-	11.01	11.27	11.8
Number of embryos obtained	-	5.18	4.94	5.18
Number of units of gonadotropin/ day	IU	167.15	215.8	205.66

Student test for the variables: age, BMI, endometrium thickness, number of oocytes retrieved, number of days of stimulation and number of embryos obtained for the

patients in the FSH and HPHG groups indicated that the mean values of these variables are not statistically significantly different.

Student test for the variables: age, BMI, endometrium thickness, number of oocytes retrieved, number of days of stimulation and number of embryos obtained for the patients in the FSH and FSH+HPHG groups indicated that the mean values of these variables are not statistically significantly different.

Student test for the variables: age, BMI, endometrium thickness, number of oocytes retrieved, number of days of stimulation and number of embryos obtained for the patients in the HPHG and FSH+HPHG groups indicated that the mean values of these variables are not statistically significantly different.

Student Test for the number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH group (group A) towards number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the HPHG group (group B) is presented in fig. 11.

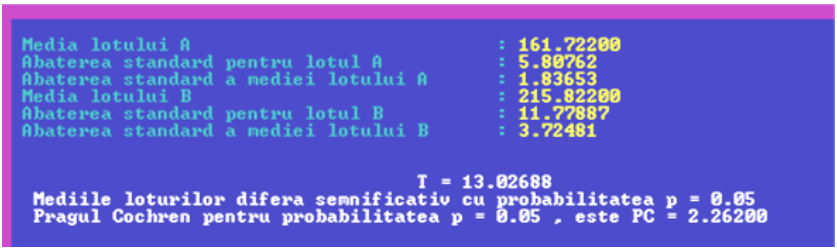

Fig. 11. Student Test for the number of units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH group towards patients in the HPHG group.

Average number of units of gonadotropin used for ovarian hyperstimulation in the FSH group (group A = 161.7 IU) is statistically significantly different from the average number of units of gonadotropin used for the HPHG group (group B = 215.8 IU) for p = 0.05.

Student Test for the number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH group (group A) towards number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH+HPHG group (group B) is presented in figure 12.

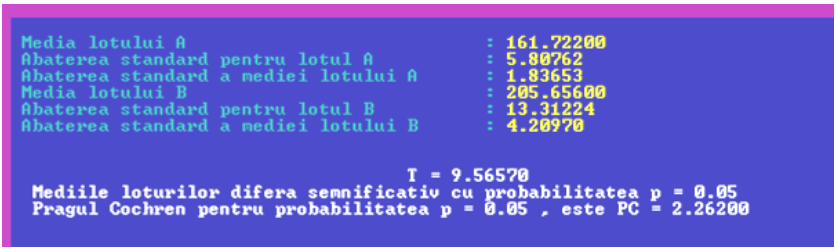

Fig. 12. Student Test for the number of units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH group towards patients in the FSH+HPHG group.

Average number of units of gonadotropin used for ovarian hyperstimulation in the FSH group (group A = 161.7 IU) is statistically significantly different from the average number of units of gonadotropin used for the FSH+ HPHG group (group B = 205.66 IU) for p = 0.05.

Student Test for the number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the HPHG group (group A) towards number of international units of gonadotropin used for ovarian hyperstimulation for the patients in the FSH+HPHG group (group B) is presented in fig. 13.

Average number of units of gonadotropin used for ovarian hyperstimulation in the HPHG group (group A = 216.24 IU) is not statistically significantly different from the average number of units of gonadotropin used for the FSH+ HPHG group (group B = 205.66 IU) for p >0.1.

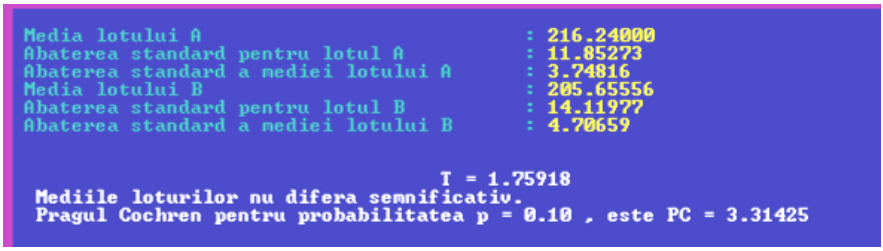

Fig. 13. Student Test for the number of units of gonadotropin used for ovarian hyperstimulation for the patients in the HPHG group towards patients in the FSH+HPHG group**.**

DISCUSSION

The data presented above pointed out that apparently IVF pregnancy prognosis, defined as the best birth/ abortion ratio is not dependent on variables such as : age, BMI, endometrium thickness, number of oocytes retrieved, number of days of stimulation, number of embryos obtained or number of units of gonadotropin used per day for ovarian hyperstimulation.

Still, when we analyzed the best birth/ abortion ratio according to the medication used for ovarian hyperstimulation we could see that the best result was obtained when recombinant FSH was used. Different variables were analyzed and the number of units of gonadotropin used per day for ovarian hyperstimulation was found to be a favorable variable for a better IVF pregnancy outcome. Statistics pointed out that less the number of units of gonadotropin used per day, better the birth/ abortion ratio for the patients where recombinant FSH was used (fig. 14).

Nowadays there are many attempts to identify any parameter that could improve IVF clinical outcome, defined as live birth rate or “baby taken home” rate. Regarding controlled ovarian hyperstimulation recent studies demonstrated the optimal number of oocytes to maximize the live birth rate (6), but few studies focused on the number of units of gonadotropin used per day. One of our previous small studies pointed out the possibility that less number of units of gonadotropin per day could mean better chances for a good pregnancy prognosis (7).

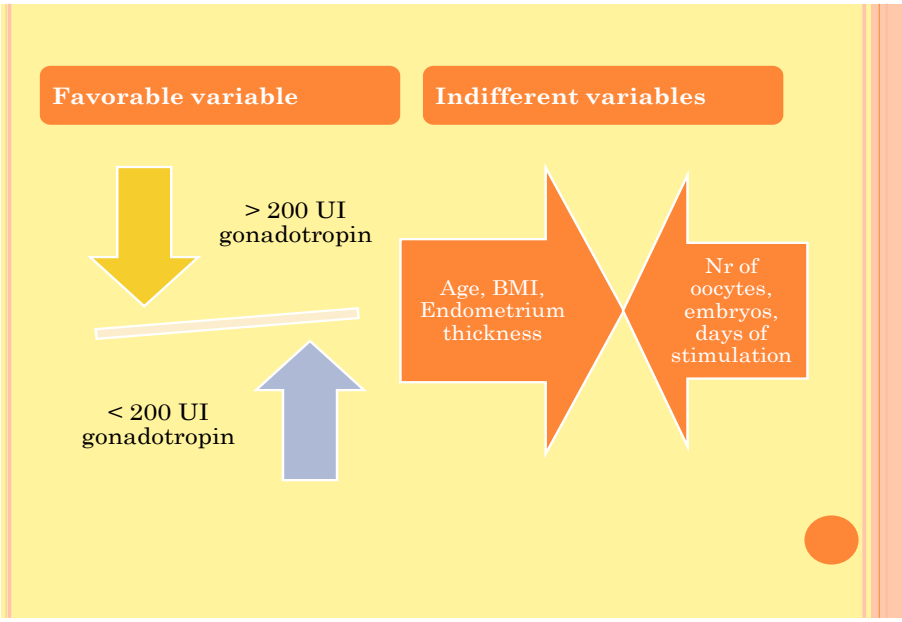

Fig. 14. Favorable variable for the best birth/ abortion rate.

CONCLUSION

The best IVF pregnancy prognosis (the best birth/ abortion ratio) was obtained when recombinant FSH was used. The majority of variables used in this study (age, BMI, endometrium thickness, number of oocytes retrieved, number of embryos obtained, number of days of ovarian hyperstimulation) are not favorable variables for this result, but the number of units of gonadotropin used per day for ovarian hyperstimulation seems to play an important role: less units of gonadotropin for the FSH group seems to be associated in our study group to a better birth/ abortion rate.

We consider that our data gives an interesting perspective upon the connection between controlled ovarian hyperstimulation and pregnancy outcome, especially these days when tendencies are to obtain as many oocytes in one procedure as we can, which often means to use high doses of gonadotropin.

BREAST CANCER RISK AND LIPID METABOLISM GENES

The breast cancer is an important pathology for women. The identification of biomarkers to highlight and differentiate between the estrogen receptor subtypes of breast cancer (sensitive or insensitive to hormones) would enable the adoption of prevention methods specific to each type of breast cancer. According to data published in Cancer Prevention Research, some genes related to lipid metabolism are related also with risk for hormone receptor-positive or hormone receptor-negative breast cancer. Khan and colleagues have analyzed by Illumina expression array and quantitative real-time PCR, the samples obtained by fine needle aspiration on the unaffected breast of women with unilateral breast cancer. The researchers identified 18 genes with high expression levels in samples from estrogen receptor-negative cases. They show that 4 genes (DHRS2, HMGCS2, HPGD and ACSL3) associated with lipid metabolism are a significant overexpression in estrogen receptor-negative cases. Another 2 genes (UGT2B11 and APOD) associated with lipid metabolism have a lower expression in estrogen receptor-positive cases. The results suggest that certain lipid metabolism genes may be potential biomarkers of different subtypes of breast cancer (Wang J, Scholtens D, Holko M, Ivancic D, Lee O, Hu H *et all*. Lipid metabolism genes in contralateral unaffected breast and estrogen receptor status of breast cancer. *Cancer Prev Res*, 2013; 6(4): 321–30).

RESISTANT HYPERTENSION: THE ROLE OF INTERVENTIONAL THERAPY

Viviana Aursulesei
University of Medicine and Pharmacy "Grigore T. Popa" – Iasi
Faculty of Medicine
1st Department of Medical Cardiology

RESISTANT HYPERTENSION: THE ROLE OF INTERVENTIONAL THERAPY (Abstract): Resistant hypertension still represents a major health problem, incompletely resolved by the current therapeutic interventions. Based on the interference of sympathetic over activity in resistant hypertension, novel invasive strategies such as sympathetic renal denervation and carotid baroreceptor stimulation have recently emerged. Despite the promising results and their good tolerability profile, the optimal role of these non-pharmacologic therapies relative to conventional medical regimens, remains unknown. Further investigation is also necessary to establish their real long-term efficacy and safety in clinical practice. **Keywords**: RESISTANT HYPERTENSION, INTERVENTIONAL THERAPY, SYMPATHETIC OVERACTIVITY, RENAL DENERVATION, BARO-REFLEX STIMULATION.

Arterial hypertension is one of the most common worldwide diseases of this century, characterized by an alarming percentage of patients with uncontrolled blood pressure (BP) values. It was estimated that 25% of adult population had arterial hypertension in 2005, and this figure is predicted to rise to 1,5 billion by 2025 (1). There is a linear relationship between BP and cardiovascular risk, accounting for 13.5% premature deaths, 54% of all cases of stroke and 47% of ischemic coronary events in worldwide statistics (2, 3). Despite the availability of various effective antihypertensive agents, target BP is not achieved in a large number of subjects.

In current guidelines, arterial hypertension is defined as resistant to treatment when the concurrent use of at least three antihypertensive drugs (mandatory a diuretic) in appropriate schemes and at maximum doses fails to optimally lower BP (4). The target values are different according to the type of hypertensive patient: < 140/90 mm Hg in general or < 130/80 mm Hg in high risk hypertension (diabetics, patients with chronic renal or ischemic coronary disease etc). The importance of the phenomena is highlighted by the prevalence of 15-20% reported in literature (5). In fact the prevalence of resistant hypertension ranges from 5% to 50% depending on the studied population or hypertension centre. For this reason the exact prevalence is difficult to determine (6-9). The direct consequences of raised BP values, respectively the significant percentage of target organ damage and particular metabolic profile, set patients at high risk for major cardiovascular events, thus making resistant hypertension a clini-

cal and epidemiological priority (10).

In clinical practice, the workup of suspected resistant hypertension involves the following steps (11):

1. to prove failure in controlling BP values irrespective of the type of measurement used: office BP, home BP or 24-hour ambulatory monitoring;

2. to differentiate true resistant hypertension from pseudoresistance caused by BP measurement artifact, white-coat effect, physician inertia, pseudohypertension, poor patient adherence to prescribed therapy because of lack of education/information or treatment regimen (inappropriate/unaffordable combinations, frequent changes in therapeutic scheme, adverse effects, high cost of medication);

3. to establish the potential causes of resistance related to:

a. medication: inadequate diuretic therapy, drug interaction (non-steroidal anti-inflammatory, corticosteroids, anabolic drugs, erythropoietin, oral contraceptives, cyclosporin, tricyclic antidepressants sympathomimetics, cocaine, amphetamines etc), inappropriate combinations/dosing, rebound effect (e.g. for clonidine), adverse effects (reflex vasoconstriction, hydro-saline retention);

b. comorbid conditions: excessive salt intake > 10 g/day, alcohol abuse, smoking>20 cigarettes/day, chronic renal disease, obesity, diabetes mellitus, sleep apnea, elderly, panic attacks, chronic disease causing pain) or ignored secondary causes of hypertension, most common renal parenchymal/renovascular disease, primary aldosteronism.

Along these lines, hypertension can be considered as true resistant and treated according this judgment only after completing the previous analysis. The complex therapeutic schemes and the new classes of antihypertensive drugs are the common option for treatment. However, it is believed that about 10% of patients will continue to be resistant although on 6-7 antihypertensive drugs (12). According to the current recommendations, if arterial hypertension was labeled as true resistant to treatment and subsequent therapy was correctly and completely applied (first and second steps), interventional therapy, which represents the third step, can be considered (13).

PHYSIOPATHOLOGICAL BASIS FOR INTERVENTIONAL THERAPY

The interference of sympathetic over activity, which is shown to be present in most cases of resistant hypertension with no secondary cause, is fundamental for developing the interventional concept (14). Based on the demographic data of Framingham and ALLHAT studies, a particular "phenotype" in resistant hypertension is suggested, in which older age, obesity, aldosterone excess and obstructive sleep apnea are covering most part of patients characteristics. It is well documented that sympathetic nervous system (SNS) activity increases with aging, especially in skeletal muscles (15). Secondly, aldosterone excess, obesity, and obstructive sleep apnea are not only common co morbid conditions in resistant hypertension, but also mechanisms which actively interact. Although not fully elucidated, SNS activation may be a major contributing factor to these interactions.

By using sophisticated techniques for the measurement of sympathetic nerve fibers activity or excess plasma norepinephrine, it was clearly documented that in normotensive obese patients efferent sympathetic fibers to the kidneys and skeletal muscle vasculature are overactive, normal to the skin and hepatomesenteric circulation, and

reduced to the heart. In obese hypertensive patient this kind of heterogeneity is depressed, while the suppression of cardiac efferent sympathetic fibers disappears. It is the visceral adipose tissue distribution that seems to be crucial for SNS activation (16). The discussed mechanisms are extremely complex, including high plasma leptin concentration, hyper-insulinemia, decreased arterial baroreflex sensitivity, but also bidirectional interaction with renin-angiotensin-aldosterone system (RRAS) which promotes inflammation, endothelial dysfunction, arterial stiffness (16-18). The increased variability of BP is the consequence of arterial stiffness, but is also a clinical marker for intensive sympathetic traffic, with negative impact on prognosis (19).

Obstructive sleep apnea, common in obesity, is also independently related to the occurrence of resistant hypertension. Although the mechanisms are elusive, the causal relationship between sleep apnea and SNS overactivation in skeletal muscle is postulated. Sympathetic stimulation during sleep and transient hypoxemia would provide the causal connection. The data are pertinent for hypoxemia, which is clearly involved in tonic chemoreflex activation of sympathetic inflows. The up regulation of endothelin A and angiotensin II receptors in the carotid body by hypoxia supports the role of these molecules as peripheral chemoreceptors and central neuromodulators (20-22).

Aldosterone excess has a reported prevalence of 17-22% in resistant hypertension (23), and the mechanism of SNS activation is becoming increasingly clear. It is experimentally documented that mineralcorticoid receptors in the paraventricular nuclei are closely linked to central sympathetic overactivity (24, 25).

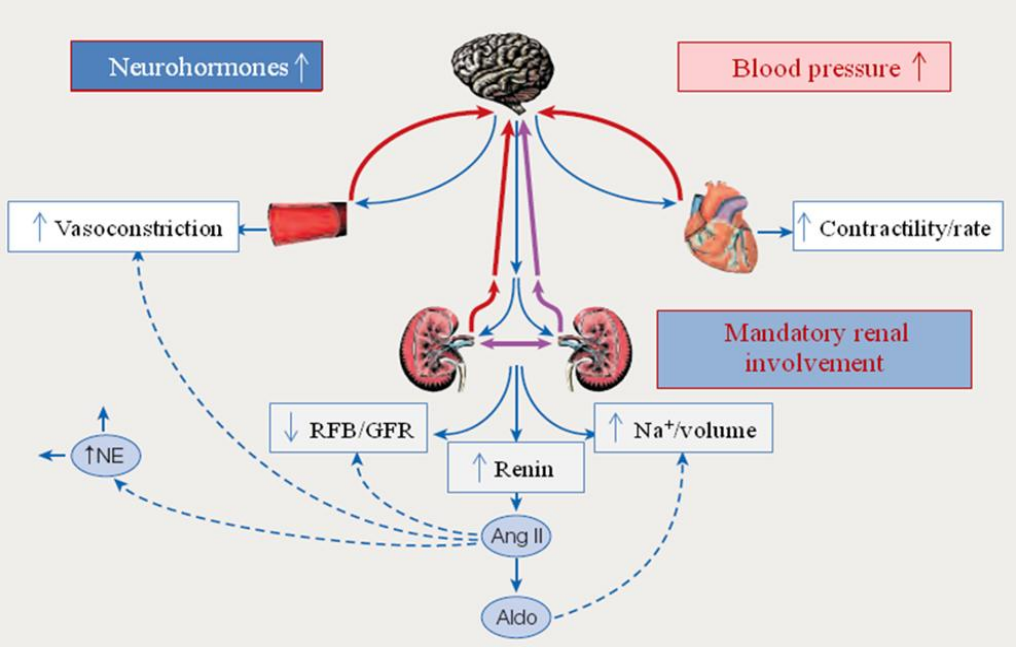

Fig. 1. Effect of SNS on BP regulation (adapted from 12). RBF – renal blood flow, GFR – glomerular filtration rate, NE – norepinephrine, Aldo – aldosterone, Ang II – angiotensin II

The role of renal sympathetic nerves lying in the adventitia of renal arteries is crucial for SNS activation. Efferent sympathetic fibers from the central nervous system activate the RRAS in juxtaglomerular apparatus of the kidneys via $ß_1$-adrenergic receptors, resulting in renin release. There is a concomitant direct stimulation of sodium and fluid reabsorption via α_2-adrenergic receptors, followed by renal vasoconstriction and a consecutive reduction in renal blood flow. Efferent sympathetic activation is linked to the development of insulin resistance, responsible for hyperinsulinemia and metabolic syndrome in over 50% of cases with resistant hypertension. At the same time, afferent sympathetic fibers maintain the central nervous system stimulation with subsequent vasoconstriction, direct structural and functional cardiac effects, hepatic gluconeogenesis (12) (fig. 1).

SYMPATHETIC RENAL DENERVATION

The sympathetic innervations of the kidneys are achieved through a dense network of postganglionic neurons which arise from the dorsal root T_{10}-L_1. The postganglionic nerves run alongside the renal arteries and penetrate the cortical and juxta medullary areas. The activation of these nerves is responsible for deleterious effects on renal hemodynamics. Renal afferent sensory nerves derive from renal pelvis and contain mechanoreceptors which respond to stretch and chemoreceptors which detect renal ischemia, hypoxia and other chemical injuries. From kidneys, the signal travels to the dorsal root ganglia T_6-L_4 and hypothalamus, area responsible for vasopressin and oxytocin release with subsequent modulation of BP level and vascular resistance (26). Electrical stimulation followed by BP elevation, mesenteric ischemia and muscle vasoconstriction is a model for afferent sympathetic fibers action. Conversely, renal afferent sympathetic denervation attenuates the effects, delays or prevents arterial hypertension in several experimental models (13).

In 1930, the overcoming of renal sympathetic stimulation consequences is first reported.

Supradiaphragmatic splanchnicectomy or radical surgical sympathectomy was applied as the last therapeutic options for malignant hypertension, resulting in over 70 mm Hg decrease of BP (12). Despite the spectacular results observed in more than 1000 hypertensive patients, including a parallel improvement of target organ damage, the surgical technique was driven to total obscurity due to severe postoperative complications (27). However, the concept was then developed in experimental studies.

The current therapeutic option is interventional renal denervation, a minimally invasive percutaneous procedure characterized by a fast effect on BP level and absence of significant systemic adverse effects (13, 26, 27). The technique requires renal angiography to assess anatomic eligibility for the procedure and to exclude renal artery stenosis. Denervation is performed using a special flexible catheter (Simplicity TM Catheter System, Ardian/Medtronic Inc.) placed into the distal segment of renal artery, and connected through its proximal end to a radiofrequency generator for ablation (27, 28). Bilateral percutaneous denervation can be accomplished in about 40-60 minutes, after at least six ablations for each renal artery (fig. 2).

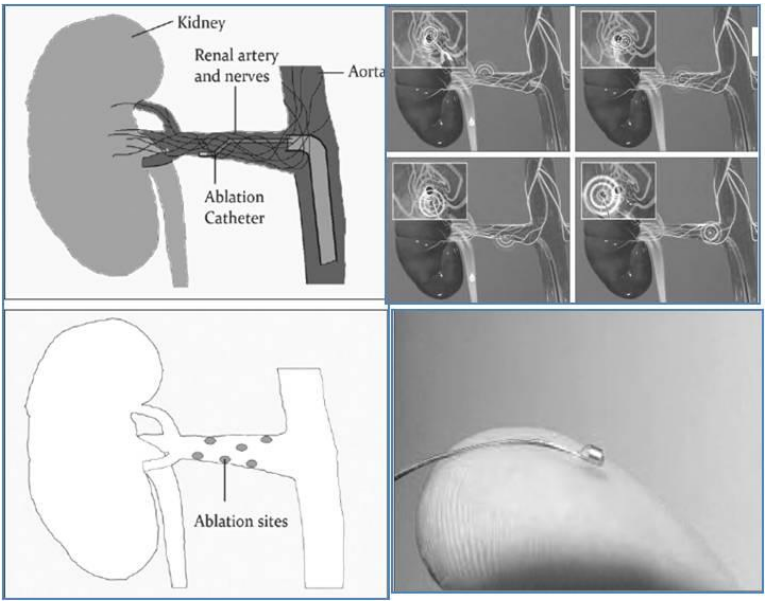

Fig. 2. Technical principle of circumferential sympathetic renal denervation using radioablation (adapted from 12, 26)

The clinical efficacy of the procedure has been proven in Symplicity Hypertension trials (HTN-1 and HTN-2) (29-31). In HTN-1 trial which included 45 patients with resistant hypertension on 5-6 antihypertensive drugs, percutaneous renal denervation induced a progressive and sustained BP decrease. After two years, mean BP was reduced by 32/14 mm Hg. The procedure was considered safe, with no complications in 97% of patients, and stable renal function. HTN-2 trial assessed 106 patients and demonstrated similar rates for BP reduction (by 32/12 mm Hg) at 6 months, with no apparent change in renal function or other significant complications.

For several reasons, the open question remains estimation of long-term procedural efficacy. First of all, renal reinnervation phenomena have been observed in experimental models, and this may attenuate procedural effect (12, 32). Secondly, ambulatory BP monitoring was performed in a limited number of patients in HTN-2 trial, and showed no significant reductions compared to office or home measurements (13). Cardio-circulatory adaptation to exercise is another problem to be evaluated, taking into account the unclear response of these patients and because SNS functional integrity is required. Finally, estimation of the benefit on cardiovascular risk may be necessary, assessing target organ damage outcome, metabolic profile, major cardiovascular events and mortality.

A successful method is subject to compliance with the eligibility criteria. The main criteria for an appropriate application of the method are an accurate practice of the first two steps for analysis and treatment of resistant hypertension, pre-procedural renal artery imaging for assessment of anatomic contraindications (e.g. CT or magnetic resonance renal angi-

ography), and a GFR > 45 ml/min/1.73 m^2. A complete sympathetic denervation is also necessary for the procedural success. From this point of view, any preprocedural efficient marker is currently missing and this could be the answer for some patients which are "nonresponders" or experience an unsatisfactory response. (33). Recently, Steigerwald and coworkers have conducted a morphological assessment of renal arteries after denervation in a porcine model. The authors have proposed optical coherence tomography imaging as a useful method for assessment of postprocedural success and immunostaining technique for neurofilament proteins detection as a relevant surrogate marker for postprocedural nervous viability (34). Finally, it is recommended the method to be performed only in very experienced centers.

A current requirement of experts is comparison of the classic method with different promising experimental procedures. It is about sympathetic denervation performed by local delivery of neurotoxic drugs, cryoablation, ultrasound-induced denervation or using different catheters (Ablation Induced Renal Sympathetic Denervation Trial study) (35). Furthermore, it is currently experimented the effect of local circumferential drugs delivery (guanetidine is the ideal agent) in adventitia of renal artery by using a special balloon catheter (Cricket™ and Bullfrog® Micro-Infusion Catheter), in order to precisely reduce renal sympathetic overactivity without harming SNS in other territories. The authors consider the multiple advantages of this method: removal of adverse drug effects, increase of therapeutic effectiveness, and improvement of patient outcomes and prognosis with concomitant decrease of medical costs (36). The method provides the perspective for treating other different hypertensive patients, including young hypertensive or patient with heart failure and chronic kidney disease (26).

BAROREFLEX STIMULATION

There are many neurohumoral reflexes which regulate the neural feedback mechanism of circulation. The arterial baroreflexes from aortic arch and carotid sinus adventitia play a key role in the short-term control of mean BP level, heart rate and contractility, vasomotor tone. Signals to the nucleus *tractus solitarius* and parasympathetic stimulation are the mechanisms involved. However, the long-term mode of action is less clear. First experimental studies have observed that baroreceptor response gradually diminishes (over minutes to days) in the face of a sustained increase in BP by "blunting" the reflex response. Although a minimal interference in chronic BP modulation has been postulated, it has been recently suggested that baroreceptors may have a substantial role by modulating renal salt excretion and, consequently, systemic fluid balance. Therefore, prolonged baroreflex activation may be responsible for BP sustained fall (36-38). Preliminary experimental studies conducted to reveal how baroreceptors function is restored, showed that carotid sinus stimulation (interpreted by the brain as a rise in BP) leads to BP decrease and reduces plasma NE level (39).

This principle has been applied in clinical practice by using a system that works in a similar fashion to a pacemaker (The Rheos CVRx Baroreflex Hypertension Therapy System). The device consists of a pulse generator which delivers activating energy of 1-7.5 V, connected to two electrodes, one for each carotid sinus, and a program-

mer system. The pulse generator is surgically implanted bellow the right clavicle (40). Recently, in Europe, a second generation miniaturized implantable system has been approved (Barosim neo^{TM} CVRx) (fig. 3).

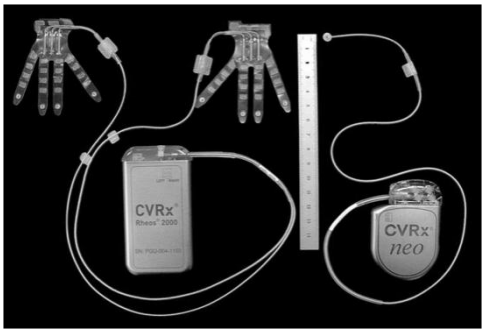

Fig. 3. Implantable baroreflex stimulators for resistant hypertension (adapted from 40)

The first clinical results have been reported by two prospective, phase II studies conducted in Europe (DE-BuT-HT) and USA (US Rheos Feasibility Trial), which documented a mean five-year decrease of BP by 53/30 mm Hg, left ventricular hypertrophy regression, and one-year renal function preservation (41-43). The beneficial results are confirmed by the recent Rheos Pivotal trial report (2011), a double-blind, randomized, prospective, multicenter, phase III clinical study of 265 patients with resistant hypertension. The trial shows a sustained drop in BP after 12 months (88% responders), the safety of method and used device. It appears that at least 6 months are necessary for achieving a sustained effect, and some procedural adverse events can occur. Simultaneously, a multicenter European study conducted by Scheffers and coworkers also demonstrates a more consistent decrease of BP measured by ambulatory monitoring, by 24/13 mm Hg after two-years of treatment, compared to renal denervation (44).

RESPeRATE® system is another type of device approved by FDA as an adjunctive therapy in resistant hypertension. The principle is based on slow and deep breathing ("paced breathing") as a trigger for baroreflex/cardiopulmonary receptors stimulation, increase of central inhibiting rhythms or decrease of chemoreceptors sensitivity (36). The direct consequence is modulation of sympathetic traffic and BP level. The system can be used in daily sessions (45 minutes per week) in order to achieve a decrease in breaths number to < 10/min. The beneficial effect has been documented in seven prospective studies, eight weeks of treatment being necessary for achieving this goal. A larger reduction in BP was observed in older patients and those with higher baseline BPs. This therapy can be combined with other pharmacologic or non-pharmacologic interventions (36).

A growing number of studies also support the significant antihypertensive effect of isometric exercises (e.g. isometric handgrip). The medical literature confirms the benefit on BP decrease after 4-8 weeks, the modulation of muscle sympathetic nerve and autonomic nervous system activity and stimulation of reactive oxygen species being involved (36). Zona PlusTM device has been designed to guide this kind of exercises, recommended to be performed in 12-minute sessions, at least three times weekly. Three randomized studies assessed the effect after at least 4 weeks of treatment and showed a mean BP decrease by 13.6/6.1 mm Hg. It appears that the effect acts in a linear fashion, with no side events (36).

In conclusion, in resistant hypertension, interventional therapy decreases sympathetic stimulation by specific mechanisms depending on each method and involves

direct, beneficial and sustained consequences on BP level, with no notable complications. Current results should be judged with caution taking account of multiple open questions in this early phase. However, the perspective for interventional methods to be used as an effective and well tolerated alternative, and also less long-term expensive for medical system, exists. Systematic and long-term follow-up of a large number of patients with resistant hypertension are the targets for new trials in progress such as Simplicity HTN-3, Global Symplicity Patient Registry or GREAT (German Renal Denervation) in order to settle the current dilemmas (26).

A PROTEIN IS LINK TO SEXUALLY TRANSMITTED INFECTIONS SUSCEPTIBILITY

The sexually transmitted infections (STI) caused especially by chlamydia and herpes simplex virus that affects the young population, predominantly female, are a global health problem. Into a study on mice, Prof. Hertzog and his team have revealed a protein called interferon epsilon (IFN-ε) with a protective effect against the viral and bacterial STI. IFN-ε is an unusual type I IFN because it is not induced by immune cells after contact with a virus or bacteria, by known pattern-recognition receptors pathways. The IFN-ε is a constitutively cytokine produced by epithelial cells of the female reproductive tract and is hormonally regulated, with the variables levels during menstrual cycle but in pregnancy and menopause with his absence. The authors of study finding that the deficit of IFN-ε is associated with increased susceptibility to STI. "Because IFN-ε follows different rules of normal immunomodulatory proteins, it might be an important link to new therapeutic opportunities for STI", noted authors of the study (Fung KY, Mangan NE, Cumming HJ et al. Interferon- Protects the Female Reproductive Tract from Viral and Bacterial Infection. *Science*, 2013; 339: 1088-1092).

LUNG CANCER – A COMORBIDITY IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE (Abstract): Chronic Obstructive Pulmonary Disease (COPD) is an important public health challenge, representing the fourth leading cause of death in the world. A very important characteristic of COPD is represented by the coexistence of comorbidities. Lung cancer, a major cause of morbidity and mortality throughout the world, is also a frequent comorbidity in COPD. Cigarette smoking represents the best-known risk factor in both COPD and lung cancer, causing common pathogenic mechanisms like oxidative stress and inflammation. However, the etiopathogenic link between COPD and lung cancer implies a common underlying genetic susceptibility, acting in addition to environmental risk factors. These trigger more complex cellular and molecular mechanisms, represented by immune dysfunction, abnormal activation of transcription factors, altered signaling pathways, epithelial to mesenchymal transition. A better understanding of the etiopathogenic link between COPD and lung cancer at the molecular level will allow the discovery of more sensitive diagnostic methods and also new molecular targets for an efficient treatment. **Keywords:** COPD, LUNG CANCER, INFLAMMATION, COMORBIDITY.

Chronic Obstructive Pulmonary Disease (COPD) is a preventable and treatable disease, characterized by persistent airflow limitation, usually progressive and associated with an enhanced chronic inflammatory response in the airways and the lung, to noxious particles and gases (1).

This disease generates an important public health challenge, representing the fourth leading cause of the death in the world, further increases in its prevalence and mortality being predicted in the coming decades (2).

One of the main characteristics of COPD is represented by the coexistence of comorbidities, with a significant impact on disease prognosis. Some comorbidities arise independently of COPD whereas most of these are causally related or share common pathogenic mechanisms.

Lung cancer represents a comorbidity frequently seen in patients with COPD and also a major cause of morbidity and mortality throughout the world. Lung cancer has been found to be the most common cause of death in patients with mild COPD (3).

Clearly, cigarette smoking represents the most common known risk factor for

COPD, and also for lung cancer. However, only a small percentage of smokers go on to develop one of these diseases in their lifetime. This situation is explained by the complex pathogenic pathways involving a common underlying genetic susceptibility generated by multiple polymorphic genes, acting in addition with known shared environmental risk factors.

This article will illustrate some evidences of the epidemiologic, cellular and molecular mechanisms involved in the etiopathogenic link between COPD and lung cancer.

1. Tobacco smoking - a common risk factor in COPD and lung cancer. The results of epidemiological studies have shown a strong association between smoking and both, lung cancer and COPD morbidity and mortality, respectively. The two chronic diseases share tobacco smoking, as an important common risk factor.

A comprehensive report on deaths from tobacco smoking between 1950 and 2000 demonstrates that smoking is associated with 90% of lung cancers, most of these arising from epithelial cells (4).

A meta-analysis of the epidemiological evidences regarding the relation between smoking and COPD, chronic bronchitis and emphysema, published in 2011, has found a elevated relative risk in current smoking (COPD 3.51, chronic bronchitis 3.41, emphysema 4.87) and ex smoking (COPD 2.35, chronic bronchitis 1.63, emphysema 3.52) (5).

2. The link between COPD and lung cancer, independent of tobacco smoking. Beyond the role of smoking as the common most important risk factor in both COPD and lung cancer, there are evidences showing towards the existence of other independent risk factors.

A large observational study confirmed the high incidence density of lung cancer in COPD (16/1000 person-years), by comparing with 1–1.5/1000 person-years in normal smokers. GOLD stages I and II, older age, lower body mass index and lung diffusion capacity of carbon monoxide (DLCO) below 80%, were associated with elevated risk of lung cancer. The incidence of lung cancer over time decreased in a stepwise manner with the increasing of the airflow obstruction severity at baseline, from disease stage GOLD I to IV (6).

DLCO, the most important physiological marker of computed tomography (CT) detected emphysema, independently associated with the diagnosis of lung cancer. CT detected emphysema, has been reported to be an independent risk factor for the development and prognosis of lung cancer (7).

A case–control study investigated COPD prevalence in lung cancer showing that COPD was more than six-fold frequently in the lung cancer group, compared with control group (8).

3. Lung cancer in never smoking COPD. 10% of the men and 20% of the women newly diagnosed with *non small cell lung cancer* (NSCLC), are never smokers. Among these cases, an overwhelming proportion is adenocarcinoma. The increased risk of NSCLC in never smokers has been associated with environmental, genetic, hormonal and viral risk factors (9).

Using the data resulting from Cancer Prevention Study II, a prospective study of cancer mortality conducted by the American Cancer Society, Turner et al. demonstrated elevated lung cancer mortality, associated with the history of emphysema, even among persons who had never been active smokers. Lung cancer mortality was significantly associated with emphysema

(hazard ratio 1.66) and with the combined endpoint of emphysema and chronic bronchitis (hazard ratio 2.44), but no association was observed with chronic bronchitis alone (hazard ratio 0.96). The association between chronic bronchitis and lung cancer was stronger in men (hazard ratio 1.59) than in women (hazard ratio 0.82) (10).

4. Bronchial obstruction, lung emphysema and lung cancer risk. A meta-analysis including population-based studies which examined the relationship between airway obstruction and lung cancer risk showed that reduced forced expiratory volume in one second (FEV1) correlated with the increased risk for lung cancer in the general population. Compared with the highest quintile of FEV1 (>100% of predicted), the lowest quintile of FEV1 (<70% of predicted) was associated with a 2.23 fold increase of the risk for lung cancer in men and a 3.97 fold increase of the risk in women (11).

In addition to airway limitation, the other defining element of COPD, emphysema, represents a strong and statistically significant independent risk factor related to lung cancer (OR, 3.14; 95% CI, 1.91–5.15). This correlation was demonstrated by CT scan assessment of emphysema (12).

A clinical research assessing the prognosis significance of emphysema, associated with lung cancer, demonstrated that the presence of emphysema, with or without airway obstruction, is related with survival, as an independent prognostic factor (HR = 1.49), for patients with NSCLC (13).

5. Stepwise histological progression towards malignancy. Epithelial to Mesenchymal Transition is the process whereby epithelial cells undergo a shift in development to a fibroblastoid or mesenchymal phenotype. Epithelial to mesenchymal transition represents an essential mechanism in normal embryonic development but also in pathologic processes like chronic inflammation and fibrosis (14).

The fragmentation of the reticular basement membrane in the airway of COPD patients appears to be a hallmark of the epithelial mesenchymal transition. A study based on endobronchial biopsies samples demonstrated a significant reticular basement membrane fragmentation and epithelial to mesenchymal transition markers increasing, in current smokers, ex-smokers with COPD and smokers with normal lung function compared with never-smoking subjects (15).

The disruption of intercellular contacts and the enhancement of cell motility, essential features of epithelial to mesenchymal transition, represent alterations suitable for migration, tumor invasion and dissemination. Several interconnected transduction/ signaling pathways have proved to be an important link between epithelial to mesenchymal transition and carcinogenesis (16).

In pathogenesis of lung cancer has been described a stepwise progression from pathological premalignant changes in the bronchial epithelium, towards basal cell hyperplasia, dysplasia and finally, towards squamous cell carcinoma.

The exposure to carcinogens from cigarette smoke damages the epithelium leading to stochastic genetic mutations at widely separated sites. A single mutant epithelial cell clone could expand and extend into widespread areas of the bronchial epithelium (17).

6. Inflammation – the pathogenic link between COPD and lung cancer. The inflammation represents an essential element in generation of the pathogenic link between COPD and the lung cancer, involv-

ing genetic and epigenetic modulations due to chronic tissue injury and abnormal tumor immunity in susceptible hosts. Tobacco smoke represents the main inducer of the inflammatory response in COPD, by providing an exogenous source of oxidative stress in the lung, which overcomes the natural defense mechanism (18).

In COPD, activated macrophages orchestrate the inflammatory process of the disease, releasing reactive oxygen species, extracellular matrix proteins, cytokines and matrix metalloproteinases, essential to the pathogenesis of emphysema and bronchial inflammation. The breakdown of extracellular matrix in parenchymal tissues occurs simultaneously followed by an increase in extracellular matrix production in the adjacent small airways (19, 20).

The macrophages may also be involved in early preinvasive lesions of lung cancer, forming dense clusters into stromal areas surrounding the tumor and producing focal breakdown of the epithelial basement membrane. In the areas of invasion where tumor-associated macrophages act, these promote cancer cell motility and metastasis. In the avascular and perinecrotic areas surrounding the tumor, hypoxic macrophages stimulate angiogenesis (21).

The increased inflammation has been demonstrated to associate a high risk for malignancy. Baseline C-reactive protein levels above 3 mg/dl seem to be a biomarker of increased likelihood of developing lung cancer (22).

Inflammatory mediators from COPD may induce proneoplastic mechanisms: production of immunosuppressive factors, cellular mutations and resistance to apoptosis, angiogenesis, invasion and metastasis. Inflammatory cells such as macrophages and T lymphocytes can communicate with the neoplastic cells through a reciprocal and self-perpetuating interaction, resulting in increased growth and resistance to immune destruction (23).

The inflammatory milieu is an important factor for tumor growth regulation. Proinflammatory cytokines, such as IL-1β, promote malignancy through immune suppression generated by induction of myeloid suppressor cells, counteracting immune surveillance and allowing the proliferation of malignant cells (24).

7. Prostaglandins in COPD and Lung Cancer. The enzyme cyclooxygenase-2 (COX-2) and its product, prostaglandin E2 (PGE 2) play a critical role in the regulation of inflammatory responses, in respiratory diseases. COX-2 gene expression and the enzyme activity are increased in the peripheral lung of COPD patients (25).

In lung cancer cyclooxygenases mediate production of prostaglandins from arachidonic acid, promoting tumor growth, angiogenesis and metastasis.

The role of COX-2 in lung cancer development was assessed by genotyping lung cancer and control subjects, for polymorphisms of the inflammation-related genes prostaglandin synthase-2/cyclooxygenase-2 (COX2/PTGS2). The results showed that carriers of the C allele of a polymorphism in the 3'-UTR region of COX2 had a significantly increased risk of lung cancer, with odds ratios of 4.28 for homozygotes and 2.12 for heterozygotes (26).

Data obtained in earlier studies, immunehistochemically staining the COX-2 protein in lung cancer, showed positivity in 90% of adenocarcinomas and in all squamous cell carcinomas (27).

The daily treatment with aspirin as COX-2 inhibitor has been found to decrease the risk of lung cancer, confined to

adenocarcinomas (28).

8. COPD and lung cancer – common intra/inter-cellular signaling pathways. The complex pathogenic relationship between COPD and lung cancer is based on inflammation mediators and some specific cell signaling pathways.

The transcription factor NF- kB promotes chronic inflammation, playing a significant role in the pathogenesis of COPD by releasing of inflammatory mediators. The inflammation is perpetuated through increased transcription of target genes encoding chemokines, cytokines and adhesion molecules and promoting cell survival (29).

NF-kB provides a critical link between inflammation and carcinogenesis, up-regulating the expression of tumor promoting cytokines, such as interleukin-6 (IL-6) or tumor necrosis factor (TNF-α), and survival genes, such as Bcl-XL. NF-kB activation is present in certain solid tumors, but no oncogenic mutations responsible for its activation in carcinomas have been identified (30). The researches demonstrated the role of NF-kB-dependent inflammatory response in inducing lower airways lung cancer in cigarette smoke exposed animals (31). NF-κB activity correlates with proneoplastic events like proliferation, apoptosis, angiogenesis and may determine chemo-radioresistance in cancer treatment (32).

- Phosphoinositol 3-kinase (PI3K) pathway is involved in many cellular functions, including cell growth, motility, proliferation, and survival. PI3K activated by cell-surface receptors, initiates intracellular signaling cascades, generating the lipid secondary messenger phosphatidylinositol-3,4,5-triphosphate (33). There is an increased expression of the PI3Kδ isoform in macrophages, in the peripheral lungs of patients with COPD, compared with healthy smokers and nonsmokers (34).

In smokers, PI3K pathway activation in bronchial dysplastic epithelium represents an early event in lung tumorigenesis. The PI3K activity remains elevated in lung cancer, independent of smoking status. The treatment with myo-Inositol, a precursor of phosphatidylinositol, may determine the regression of airway dysplasia by inhibition of PI3K, associated with increased expression of genes that are repressed on PI3K activation (35).

Signal Transducer and Activator of Transcription (STAT3) is a molecule with an important role in regulating cytokine-dependent tumor-promoting inflammation and transducing signals from various oncogenic pathways. STAT3 promotes pro-oncogenic inflammatory pathways, including nuclear factor NF-kB and IL-6 (36).

IL-6 is one of the main causative agents of emphysema, through inducing apoptosis in the lung (37). IL-6 and STAT3 are co-expressed in alveolar type II epithelial cells in the lung. The increased IL-6 levels in exhaled breath condensate reflect airway inflammation in patients with COPD (38). STAT3 signaling plays an important role in initiation and progression of pulmonary adenocarcinoma. The averages of STAT3 up-regulated gene expression levels are 2-fold to 8-fold higher in human adenocarcinomas, in comparison with normal subjects (39).

STAT3 also regulates the expression of MUC1, a gene which mediates tumorigenesis, lung cancer cell survival and metastasis (40).

Epidermal growth factor receptor (EGFR) overexpression is one of the earliest abnormalities in the bronchial epithelium of high-risk smokers. It is present at the stage

of basal cell hyperplasia and persists through squamous metaplasia, dysplasia, and carcinoma in situ. EGFR overexpression is found in all squamous carcinomas and in 65% of adenocarcinomas and may link airway inflammation from COPD to lung carcinogenesis (41).

CONCLUSIONS

Lung cancer represents an important comorbidity in COPD, dramatically increasing the mortality of this disease.

Cigarette smoking is the most important risk factor, underlying the pathogenic link of the two diseases, triggering common pathogenic mechanisms involving oxidative stress, chronic inflammation, immune dysfunction, abnormal activation of transcription factors, altered signaling pathways, epithelial to mesenchymal transition.

A greater understanding of the molecular and cellular pathobiology and common signaling pathways involved in COPD and lung cancer will allow the discovery of more sensitive diagnostic methods and also new molecular targets for an efficient treatment.

RESIN-COMPOSITE CYTOTOXICITY VARIES WITH SHADE AND IRRADIANCE

The study was aimed at investigating the cytotoxicity of different composites as a function of composite shade and the light curing unit employed. Non-polymerized and polymerized samples of the composites Grandio® (VOCO,Cuxhaven), Solitaire® (Heraeus Kulzer, Hanau) and Filtek Z 250® (3M/Espe, Seefeld) in two markedly differing shades (A2, C2) were prepared. Polymerization was performed with two light curing units: Heliolux II (Ivoclar/Vivadent, Ellwangen) and Swiss Master Light (EMS, Nyon, Switzerland). To obtain composite extracts, the samples were immersed in cell culture medium (DMEM – Dulbecco‘s Modified Eagle Medium), which was replaced daily up to the 7th day of the experiment, and then on the 14th, 21st and 28th day. After incubation of human gingival fibroblasts with the extracts obtained, cytotoxicity was determined using the MTT test. With the non-polymerized samples, essentially no influence of the composite shades investigated on fibroblasts viability was detected, with the exception of the Solitaire material, where a higher cytotoxicity of the shade C2 in the non-polymerized state was found at the end of the observation period. After polymerization of the different composites, the cytotoxic reaction observed for the extracts of shade C2 was stronger than that observed for A2. After polymerization with the Heliolux II, the extracts of composites Grandio and Solitaire C2 were significantly more toxic than those of the A2 shade ($p < 0.01$). Polymerization with the Swiss Master Light reduces this cytotoxic effect. The extracts of the Grandio composite showed the least cytotoxic effect throughout the observation period, irrespective of the curing unit used. For the extracts of the Z250 specimens, the cytotoxicity observed was generally higher. These results show that the shade of the composite has an influence on its cytotoxicity and that this cytotoxicity is also influenced by the light curing unit used. It was observed that composites of the darker shade (C2) had a higher cytotoxicity, which varied with the light curing unit employed (Bernd W. Siguscha, Torsten Pflauma, Andrea Völpela, Kerstin Gretscha, Sandra Hoya, David C. Watts, Klaus D. Jandt. Resin-composite cytotoxicity varies with shade and irradiance. *Dental Materials* 2012; 28: 312-319).

SOCIO-DEMOGRAPHIC AND LIFESTYLE CHARACTERISTICS ASSOCIATED WITH THE RISK FOR OBSTRUCTIVE SLEEP APNEA SYNDROME IN A RURAL POPULATION (Abstract): **Aim:** To evaluate socio-demographic and lifestyle characteristics in relationship to the risk for obstructive sleep apnea syndrome (OSAS). **Material and methods:** The study was carried out on 254 subjects**.** Socio-demographic data (age, gender, occupation, education level, and economic status), smoking status, alcohol consumption, and hours/day spent watching TV were recorded. For physical activity assessment the International Physical Activity Questionnaire and for identifying the risk for OSAS Berlin Questionnaire were used. **Results:** Of the 254 subjects, 29.4% of men and 36.8% of women were at high risk for OSAS (p=0.22). Age was higher in the group at high risk for OSAS (p=0.002) and in women (p<0.001). The highest percentage (47.5%) of participants at high risk for OSAS was found among retired people, whereas farmers generated the lowest percentage (18.6 %) (p<0.001). 57.1% of retired women were at high risk for OSAS as compared to 5.6% of the farmers (p<0.001). Education level and monthly income did not influence the risk of OSAS (p=0.172, p=0.113, respectively). No differences in the risk of OSAS were found in relation with smoking (p=0.887), alcohol consumption (p=0.688), and sedentary lifestyle. We found that individuals at low risk for OSAS performed more physical activity at work (p=0.053) and significantly more vigorous physical activity (p=0.036). **Conclusions:** In the study rural population, age, occupation and physical activity are related to the risk for OSAS. **Key words:** OBSTRUCTIVE SLEEP APNEA SYNDROME, SOCIO-DEMOGRAPHY, LIFESTYLE, PHYSICAL ACTIVITY.

Obstructive sleep apnea syndrome (OSAS) is an increasingly prevalent sleep disorder characterized by repetitive episodes of upper airway obstructions leading to sleep fragmentation and excessive daytime sleepiness (1). One of the first studies to evaluate the prevalence of OSAS estimated it to be about 4% of men and 2% of women (2). Later on, the same author found that a very high proportion of the general adult population is undiagnosed (3) and a decade later, he estimated that the prevalence of OSAS in adults 30 to 69 years of age is approximately 17% (4).

Evidence from several studies reveal that undiagnosed and untreated OSAS is independently related to increased mortality rates (5), traffic accidents (6), diminished quality of life (7), and work disability (8). Strategies to increase the diagnostic rates and the detection of risk factors for OSAS need to be developed. Excess weight represents the strongest risk factor for OSAS (4) but other risk factors have been cited, including age, gender, family history, smoking, alcohol, and menopause. The social and cardiovascular consequences of OSAS seem most pronounced among patients of low socioeconomic status (9).

Among potentially modifiable risk factors, the ones related to lifestyle, namely excess weight, alcohol, smoking, could represent targets for health policies. Even though data suggest that obstructive sleep apnea is associated with these factors, the only evidence-based intervention strategy is weight loss (10), hence the usefulness of weight control and increased physical activity, as a preventive measure or even as a treatment for OSAS. The aim of this study was to evaluate the socio-demographic factors including age, gender, occupation, education level, economic status, and some elements of lifestyle (smoking, alcohol consumption, sedentary lifestyle and physical activity) in relation to the risk for OSAS in a rural population.

MATERIAL AND METHODS

We conducted a cross-sectional study on 254 subjects in Deleni, the largest rural community in Iași County. The subjects were randomly selected from a database of 3248 individuals created during the 2007-2008 National Health Programs, the study sample being representative for this population (11). All participants signed a written informed consent before enrolling, and the study had the approval of the University Ethics Committee.

The following data were recorded during an interview: socio-demographic data (age, gender, occupation, education level, and monthly income/family member), smoking status, and alcohol consumption - each type of alcohol being assessed separately. According to smoking habit subjects were divided into 3 groups: non-smokers, former smokers (over 6 months abstinence) and current smokers. Alcohol consumption of more than 3 servings/day for men and more than 2 servings/day for women was considered to be excessive (1 serving = 50 ml strong alcoholic drink =150 ml wine =350 ml beer).

The assessment of physical activity was done by using the International Physical Activity Questionnaire (IPAQ) – long form (12), which measures the intensity and duration of physical activity performed during the last 7 days, in 4 domains: at work, during transportation, household activity (domestic), and during leisure time, or exercise. The results were expressed in two different ways: as continuous variables, in MET-minutes/week (total and for each activity), and category variables, establishing if the subjects were sedentary, moderately active or active. Sedentary lifestyle was evaluated using two separate tools: number of minutes/day spent sitting, regardless of the level of physical activity (item included in IPAQ), and number of hours/day spent watching TV.

The risk for OSAS was evaluated using Berlin questionnaire (13), which consists of 10 items organized in 3 categories, referring to snoring and witnessed apneas, daytime sleepiness, and the presence of either hypertension or a body mass index ≥30

kg/m^2. The risk for OSAS is high if two or more categories are positive and, by opposite, the risk is low if less than two categories are positive.

The statistical package SPSS version 17.0 for Windows (Chicago, IL, USA) was used for data analysis. The significance of differences between continuous variables was assessed using the *t* Student, One-way ANOVA, or Kruskal-Wallis tests, and for categorical variables Pearson Chi-Square test. A *p* value <0.05 was considered to be statistically significant.

RESULTS

Descriptive statistics of the studied population

Of the 254 subjects included in our study, 102 were males (40.2%), and 152 females (59.8%). The mean age was 54.75±16.9 years, with no statistically significant differences between men and women (p=0.824). Regarding occupation, almost half of the subjects were retired (48%), the remainder being farmers (16.9%), employees (14.6%), and housewives or unemployed (18.4%). As to education level, approximately 60% of the subjects were with 8 or less years of education, and only 17.3% with over 10 years of education. The per capita monthly income was in the majority of our subjects (72.4%) of ≤400 Lei/month; 53.9% with a per capita monthly income of 100-400 Lei, and 18.5% <100 Lei/family member. Only 6.7% of the study subjects reported excessive alcohol consumption. When assessing smoking status, the results showed that 14.6% of the subjects were current smokers and 7.1% former smokers.

Relationship between socio-demographic factors and risk for OSAS

No gender differences in the percentage of subjects at high risk for OSAS were found (χ^2=1.505, p=0.22) – 29.4% of men and 36.8% of women being at high risk for OSAS. In the group of subjects at high risk for OSAS, age was significantly higher than in those at low risk (p=0.002), namely 59.24±13.32 yrs, as compared to 52.45±17.14 yrs.

This difference was noticed only for women (p<0.001) – 61.23±12.19 years, as compared to 50.68±16.47 years (tab. I). Differences were observed in the percentage of participants at high risk for OSAS in relation to occupation (χ^2=20.782, p<0.001), the highest percentage (47.5%) being registered among retired persons, while the lowest percentage among farmers (18.6 %). When analyzing by gender, a statistically significant difference was found only for women, (χ^2=25.861, p<0.001), 57.1% of retired women being at high risk for OSAS, as compared to 5.6% of the farmers. Education level had no influence on the risk of OSAS (χ^2=4.992, p=0.172), neither in men (χ^2=1.034, p=0.793), nor in women (χ^2=5.676, p=0.129), the same being also true for the monthly income (χ^2=5.978, p=0.113).

Relationship between lifestyle characteristics and risk for OSAS

Smokers had no higher risk for OSAS than non-smokers (χ^2=0.24, p=0.887). No differences were observed regarding alcohol consumption between the two groups, at high risk and low risk for OSAS, respectively. Only in women, the results showed that those at high risk for OSAS drank less alcohol (0.2038±0.358 servings/day as compared to 0.3423±0.636 servings/day, p=0.046) (tab. I). We found that individuals at low risk for OSAS performed more physical activity at work than those at high risk - 1898.61±3843.744 METS/week compared

to 1106.72±3161.272 METS/week, differences with a trend towards statistical significance (p=0.053) - and significantly more vigorous physical activity (p=0.036), meaning 1037.61 ±2399.858 METS/week compared to 589.83±1964.142 METS/week. Men at low risk for OSAS do more physical activity by walking than those at high risk (p=0.016) - 1859.71±1884.661 METS/week vs. 845.43±1134.006 METS/week (tab. I).

TABLE I

Significant value of mean differences in relation with the risk for OSAS

	Total	**Men**	**Women**

DISCUSSION

The majority of population-based studies that have estimated gender specific prevalence reported a 2- to 3-fold greater risk of OSAS in men compared to women (14). Some researchers showed that gender differences lie in the anatomic structure of the upper airway, and pattern of fat deposition (15). Also, the role of sex hormones in OSAS pathogenesis and the increasing prevalence of OSAS in postmenopausal in women, incriminating a protecting role of estrogen hormones (16), have been proposed to explain the higher male risk for OSAS. Our results are in disagreement with the current literature findings: a high risk for OSAS was found in a higher percentage of women, but without statistical significance. A possible explanation could be that in this population, as previously shown, all OSAS symptoms were more frequently reported by women (17), whereas most studies reveal that women underreport specific symptoms (18) or present with complaints suggestive of other disorders than OSAS (19).

Several studies have found OSAS to be highly prevalent in people older than 60 years. In our study, age was significantly higher in subjects at high risk for OSAS, but the statistical significance was noticed only for women. Similar to our findings, observational studies that have used polysomnographic recordings as a diagnostic method showed that age was higher in women with OSAS (19).

Excessive daytime sleepiness is a noticeable problem because it affects the ability to work at best performances and in safety. Assessment of the risk factors and

symptoms of OSAS is therefore important to prevent productivity loss and work-related accidents (20). In the Wisconsin Sleep Cohort Study, OSAS severity was significantly, but weakly related to diminished psychomotor efficiency (21). With respect to occupation, our results showed statistically significant differences in the percentage of subjects at high risk for OSAS, the highest percentage of being recorded among retired persons, and the lowest among farmers. This association was investigated in several studies, showing that individuals without occupation have a higher frequency of OSAS (18).

The study conducted by Tarasiuk et al. revealed that low socioeconomic status was found to be a novel independent risk factor for cardiovascular disease among adult OSAS patients requiring treatment (22). According to our results, education level and economic status did not influence the risk for OSAS, although there is evidence that daytime sleepiness is associated with a lower education level (20). In another study, socioeconomic status and occupation had a minor effect on the likelihood that the population was hospitalized for OSAS (23).

In our study, no differences were recorded regarding alcohol consumption and smoking status in subjects at high and low risk for OSAS. Only in women, we found that those at high risk for OSAS consumed less alcohol, but the analysis was not adjusted for obesity or postmenopausal status. Alcohol ingestion has been demonstrated to increase the number of apneal episodes (24).

Smoking represents one of the strongest risk factors for cardiovascular disease and although the association with OSAS is relatively weak, it may add to the cardiovascular risk associated with OSAS (25). Wetter et al. (26) found that current smokers were three times more likely to have OSAS than never-smokers. However, former smokers were not more likely to have OSAS than never-smokers.

Physical inactivity is a risk factor for obesity, which is known to be the most important risk factor for OSAS. It has been previously demonstrated that, in our study population, the high risk for OSAS is associated with obesity, both in men and women (27). An analysis from the Wisconsin Sleep Cohort Study (28) examined this association and estimated that, in persons with mild OSAS, a 10% weight gain increased 6-fold the odds of developing moderate or worse OSA. The results of our study showed that individuals at low risk for OSAS performed significantly more vigorous physical activity. Our results are in agreement with those of the Sleep Heart Health Study which showed that at least 3 h/week of vigorous physical activity reduced the odds of sleep disordered breathing (29).

CONCLUSIONS

The results of our study show that of all assessed socio-demographical characteristics only age and occupation were associated with a high risk for OSAS. Women at high risk for OSAS were older, the highest percentage being represented by retired women.

Of the studies lifestyle features, only physical activity showed significant influence on the risk for OSAS - individuals at low risk for OSAS performed more physical activity at work and significantly more vigorous physical activity. Men at low risk for OSAS performed more physical activity by walking than those at high risk for OSAS.

NEWS

THE PLASMA LEVELS OF CAFFEINE AND THE COGNITIVE STATUS

The recent researches suggest that the consumption of caffeine and coffee may be protective against the development of Alzheimer's disease. A new case-control study evaluated the degree to which initial plasma caffeine and cytokine levels would predict changes in cognitive status. Two separate cohorts were cognitively assessed and a blood sample was taken for determination initial level caffeine/ cytokine. Over the next 2 to 4 years, researchers annually reassessed the cognition of the participants (normal, mild cognitive impairment (MCI), dementia) and the level caffeine/ cytokine. Plasma caffeine levels at study onset were lower (-51%) in MCI subjects who later progressed to dementia compared to levels in stable MCI subjects. The study showed that a 1200-ng/mL plasma caffeine level appears to be an important threshold for avoided progression MCI to dementia. Patients with MCI may be able to avoid developing dementia by drinking 5 cups coffee daily or amount 500 mg of caffeine. The research also suggests that 3 cytokine (granulocyte colony-stimulating factors (G-CSF), interleukin-10 (IL-10), and interleukin-6 (IL-6)) could be signal for impending conversion to dementia among those with MCI. The MCI subjects who later progressed to dementia, but not stable MCI subjects with high plasma caffeine levels, had reduced plasma levels of G-CSF, IL-10, and IL-6. The scientists concluded that results provided the first direct evidence that caffeine or coffee intake is associated with a reduced risk for dementia or delayed onset of dementia, particularly for those who already have MCI (Chuanhai Cao, David A. Loewenstein, Xiaoyang Lin et a . High Blood Caffeine Levels in MCI Linked to Lack of Progression to Dementia. *J Alzheimer Dis*. 2012;30:559-572).

EMERGENCE OF A NEW GROUP CTX-M ENZYME IN ROMANIA AND RISK FACTORS FOR EXTENDED SPECTRUM BETA-LACTAMASES PRODUCING *E. COLI* INFECTIONS (Abstract): Antibiotic resistance rates in *E. coli* are rapidly rising, with worrisome aspects especially regarding community - acquired resistance to third- and fourth-generation cephalosporins and fluoroquinolones. The objectives of this prospective cohort study was to determine the resistance profile of *E. coli* for two categories of patients (<49 years and ≥ 50 years), risk factors for ESBL positivity and to investigate the molecular epidemiology of ESBL type CTX-M enzymes. A total of 885 strains of *E. coli* were isolated in the Infectious Diseases Hospital laboratory between June 2008 and June 2011 and *E. coli* resistance due to ESBL production was noted in 17% of cases. We found that previous therapy with cephalosporins, hospitalization and urinary catheter were risk factors for ESBL positivity. We noted significant differences concerning resistance rate between patients under 49 years and aged more than 50 years for ciprofloxacin (19% and 38%, respectively, p=0,0001), for gentamicin (15% and 23%, p=0,008), ceftazidime (15% and 24%, p=0,001) and ESBL positivity (14% and 20%, p=0.009). This study highlights the predominance of CTX-M producing strains (92.5% of ESBLs-positive *E. coli* harboured *bla* CTX-M genes); CTX-M-15 producing isolates were the most common, accounting for 96 % of isolates. Only 4% were belonging to CTX-M group-9, an emerging ESBL group which is newly described in Romania. **Key words**: *ESCHERICHIA COLI*, RESISTANCE, CTX-M ENZYMES

A problem of global magnitude is represented by the dissemination of Gram-negative bacteria genes which codify extended-spectrum β-lactamase (ESBLs), enzymes of particular clinical and epidemiological interest that can rapidly hydrolyse, or confer resistance to oxyiminocephalosporins (extended spectrum cephalosporins and monobactams) but not carbapenems.

The emergence of extended-spectrum β-lactamases (ESBL)-producing strains mainly with CTX-M-type enzymes in the community, is an alarming phenomenon that could have major implications for antimicrobial therapy (1, 2, 3).

A lot of reports confirmed that CTX-M (frequently CTX-M-15) are associated with an important number of mobile resistance genes and that these genes have the ability to disseminate between different strains of

Escherichia coli (4)**.**

In our region of North-Eastern Romania there were no studies to evaluate risk factors such as previous treatment with cephalosporins or fluoroquinolones, presence of urinary catheters, hospitalizations during the previous 6 months, and age (>50 years) for developing an infection with ESBL-producing *E.coli* strain.

Therefore, the aim of our study was to asses all these risk factors and also**,** to investigate the molecular epidemiology of ESBL enzymes**.**

MATERIAL AND METHODS

Design of the study

The study was performed at a University Hospital of Infectious Diseases of Iasi, Romania. A total of 885 *E. coli* strains were isolated from different infections (predominantly from urine) during June 2008 and September 2010. Antimicrobial susceptibility testing was performed according to the CLSI criteria by disk diffusion method and using ATB G- strips (bioMerieux, France). ESBL production was confirmed by CLSI disc diffusion and Etest (5). Molecular characterization was done using polymerase chain reaction (Palm Cycler Corbett Research) and sequencing of *bla* CTX-M (Beckman Coulter CEQ8000) (6).

A t-test, Fisher's exact test or Pearson chi-square test was applied where appropriate, and a p-value of < 0.05 was considered to be significant.

RESULTS

The overall resistance rate for *E. coli* to cefotaxime, ceftazidime, ceftriaxone, amoxicillin - clavulanate, ciprofloxacine, gentamicin and amikacin was 34%, 27%, 43%, 36%, 30% , 27%, and 14%, respectively.

E. coli resistance due to ESBL production was identified in 17% of cases (157 strains).

Use of fluoroquinolones in the preceding 6 months were noted in 9% of the ESBL-positive patients (14 cases) and in 3.2% in the non - ESBL group (23 cases) (p=0.001). Previous treatment with a third - generation cephalosporin was described in 6.4% of the ESBL-positive patients (10 cases) and in 1.1% in the non - ESBL group (8 cases)(p=0.0001) (tab. I).

42% of patients with an ESBL – positive *E. coli* infection (47 patients) and 15% of patients from ESBL-negative group (97 patients) were hospitalized in the previous 6 months (p=0.001). Statistical analysis demonstrated that previous therapy with cephalosporin; hospitalization and urinary catheter were risk factors for ESBL positivity.

TABLE I

Risk factors for ESBL – producing *E. coli* infections

	ESBL negative	ESBL positive	p
Previous fluoroquinolone treatment	23 (3.2%)	14 (9%)	0.001
Previous third generation cephalosporins treatment	8 (1.1%)	10 (6.4%)	0.0001
Urinary catheter	19 (2.6%)	16 (10.2)	0.0001
Previous hospitalization	109 (15%)	62 (40%)	0.001

The rates of resistance for two cathegories of patients (<49 years and ≥ 50 years) are shown in Table II.

Among ESBL negative *E. coli*, resistance rate to cefotaxime or ceftazidime was up to 9%.

TABLE II
Rates of resistance according to age*

	< 49 years (n=381)(%)	≥ 50 years (n=504) (%)	p-Value
Ampicillin	256/371 (69) *	260/486 (74)	0.2
Ceftazidim	53/346 (15)	112/464 (24)	0.001
Cefotaxime	56/310 (18)	124/437 (24)	0.001
Amoxicillin-clavulanic acid	64/368 (17)	110/439 (22)	0.15
Piperacillin-tazobactam	2/121 (1.7)	4/149 (2.5)	0.49
Ciprofloxacin	71/372 (19)	188/494 (38)	0.0001
Gentamicin	50/332 (15)	106/455 (23)	0.008
Amikacin	3/80 (4)	11/220 (9)	0.2
ESBL - positive	53/381 (14)	104/504 (20)	0.009

*Data are present as no. of strains/total of tested strains (%)

We noted significant differences concerning resistance rate between patients under 49 years and aged more than 50 years for ciprofloxacin (19% and 38%, respectively, p=0,0001), for gentamicin (15% and 23%, p=0,008), ceftazidime (15% and 24%, p=0,001) and ESBL positivity (14% and 20%, p=0.009).

Molecular analysis by PCR performed in 157 ESBL positive strains revealed that 145 of ESBL-positive isolates (92,4%) harboured *bla* CTX-M gene and 12 (7,6%) were negative for this gene (non-CTX-M ESBLs). Analysis with specific primers showed that 139 (96%) of CTX-M belonged to group-1 (sequenced as type CTX-M-15) and in 6 cases (4%) CTX-M belonged to group-9. No producers of other group CTX-M enzymes were detected.

DISCUSSION

ESBL – positivity in our study was found to be higher than the rate reported by EARSS and exceeded the rate comunicated in a recent study in Turkey (11%) (7, 8). *E.coli* resistance to fluoroquinolones of more than 25% was reported in Italy (38%), Cyprus (45%), Turkey (52%) and Hungary (26%) (8).

Several recent reviews have detailed how CTX-M beta-lactamases have become dominant among extended spectrum beta-lactamases producing *E. coli* in many European countries, but data from Romania are very limited. In our study CTX-M group-1 producing isolates was the most common accounting for 96 % of isolates. Only 4% were belonging to CTX-M group-9 extended spectrum beta-lactamases.

Similar with molecular findings from our study, an absolute predominance of CTX-M group-1 was reported in Italy and in the London area (9, 10). CTX-M group-9 is the predominant group in Spain (2).

The emerging strains of *E. coli* producing CTX-M group-9, for the first time being recently described in Romania only in one strain by Tuchilus *et al* (11), may reflect introduction via foreign travel, or by food imported from other countries where the genotypes belonging to this group are very frequent (12). In our study sequencing 200 pairs of bases belonging to CTX-M-9 revealed a high degree of similarity with the fragment of CTX-M-113 described in a Shigella strain in China (13), but, subsequently, further investigations are necessary for a complete description of the gene.

Our results are in accordance with previous data reporting that the major risk factors for ESBL type resistance is antibiotic use in the preceding 6 months but we have also

demonstrated the implication of urinary catheterization, previous hospitalization and age more than 50 years as risk factors (7).

A notable limitation to our study is the limited epidemiological data about travel history and food or water exposure especially in those patients with group-9 CTX-M enzymes.

CONCLUSIONS

Our data contributed to the epidemiological and molecular investigations of antibiotics resistance of *E. coli* in Romania, with a great clinical impact concerning optimization of first intention therapy.

This study highlights the predominance of ESBL-type CTX-M producing strains, reveals that CTX-M-15 is preponderant and shows that CTX-M group-9 has emerged in Romania being described only in the North-Eastern region.

DIFFICULTIES IN DIAGNOSIS AND TREATMENT OF CHALAZIA IN CHILDREN. CASE REPORT (Abstract). Chalazion is a granulomatous inflammation caused by blocking the Meibomian glands, which affect the eyelids, predominantly the upper ones. The purpose of this article is to highlight the clinical and histopathological aspects of chalazia at children. This paper is a retrospective study of a child, 3-year-old, who presents with multiple upper and lower eyelid chalazia in both eyes, mechanical ptosis, blepharospasm and ocular pain. The history of the disease begins 2 months ago with the initial RE (right eye), for which it received general antibiotic and local treatment for 10 days with unfavorable evolution. The child was subsequently examined by another physician recommending topical treatment with Sinerdol (Rifampicin) and Dexamethasone, and empirical treatment consisting of applying a wooden spoon to injuries and hot compresses. Inappropriate treatment has led to an unfavorable evolution, and its continuing may lead to several local complications. After attempting to identify other etiologies, surgical excision was performed with slow favorable evolution. Postoperatively, general and local antibiotic and anti-inflammatory treatment with slow development was recommended. Appropriate treatment initiated from onset would have limited the extension of the chalazia; with the possibility of avoiding the surgical risk involved in general anesthesia. **Conclusions:** Ophthalmologists should consider acne rosacea as a potential diagnostic for any child who has any combination of Meibomian disease, chronic blepharitis, recurrent chalazion and chronic symptoms of photophobia, eye irritation and redness that does not respond to routine medical treatment. **Keywords:** CHALAZION, CORTICOSTEROID, ACNE ROSACEA, QUALITY OF LIFE.

Chalazion is a focal inflammation of the eyelids resulting from a obstruction of the Meibomian glands (an internal posterior hordeolum). Meibomian glands are sebaceous glands, located in the tarsal region of the upper and lower eyelids. Obstruction of the opening of the gland at the level of the palpebral margin may lead to accumulation of the tarsal and neighboring soft tissue collection, accompanied by an inflammatory reaction with pain and skin erythema. The clinic is a benign, well defined, palpable, congestive nodule that can grow. It is often confused with a palpebral carcinoma. Affection is often associated with reddish acne and chronic posterior blepharitis (1, 2). It is considered the most common benign eyelid tumor. The exact role of *Staph-*

ylococcus aureus in chalazion is not fully understood (1, 2, 3, 4). It is often confused with a palpebral carcinoma (1, 5, 6). Excision of a specimen and hematoxylin staining, histopathological examination may reveal characteristic changes (1, 5, 6). Affection is often associated with reddish acne and chronic posterior blepharitis. It tends to begin in childhood as a facial skin eruptive in response to stress.

Diagnosis is difficult to put on, it is good to consider a child with meibomitis, chronic blepharitis and recurrent chalazion. Due to diagnostic confusion and therapeutic behavior it may vary. Studies often show that multiple pseudo-tumoral formations are highlighted, recurring questions as to whether they are associated with systemic ailments and require investigation of the case in identifying a possible collateral cause (2-8). Higher location may cause a mechanical ptosis to induce a decrease in visual acuity. In the infant, any untreated form of palpebral formation accompanied by mechanical ptosis may lead to amblyopia, with long-term impairment of visual acuity and quality of vision and life will be modified (9). Also, the therapeutic behavior can vary. Initial treatment in acute inflammation is the application of warm compresses and palpebral hygiene, the antibiotic associated with local anti-inflammatory is useful when secondary infection occurs but does not completely solve the disease.

Occasionally, in chronic inflammation, the incision is the best solution, with removal of the inflammatory collection and excision of the inflammatory tissue adjacent to the collection (1, 2, 10). Multiple studies compared conventional treatment vs intralesional injections of corticosteroid, the results being similar in some studies, others inclining the balance in favor of injections that would be considered more effective and safer. They recommend corticosteroid injection in children and patients with local anesthetic allergy, and surgery in large, multiple and recurrent chalazia (10, 11, 12). Other studies suggest that the association of the incision of the formation with the local corticosteroid injection provides the resolution of the inflammation in 95% of cases (1, 10). An appropriate initial treatment could prevent the spread of inflammation in both eyelids and the appearance of local complications.

CASE REPORT

We will present a case of a 3-year-old patient who presents with multiple upper and lower eyelid chalazia, mechanical ptosis, blepharospasm and eye pain (fig. 1), for both eyes (BE). Diagnosed two months ago at RE (right eye) with upper eyelid chalazion for which she followed general treatment with oxacillin and topically with chloramphenicol, a 10-day period with unfavorable evolution.

Fig. 1. Biomicroscopy of anterior pole (multiple inflammatory formations at upper and lower eyelid)

He was subsequently consulted by another physician recommending topical treatment with Sinerdol (Rifampicin) and Dexamethasone, and empirical treatment consisting of applying a wooden spoon to injuries and hot compresses. Inappropriate treatment has led to an unfavorable evolution, and its continuing may lead to several local complications. From her personal history we mention atopic dermatitis and needed to be mentioned that her mother shows reddish acne. The specialized exam revealed: VABE = 1fcnc (visual acuity, both eyes), at the anterior pole focal inflammatory formations, mobile on the underlying, confluent planes, painful located at the upper and lower eyelid, mechanical pythosis, the orifices of prominent Meibomiam glands, congestive conjunctiva. Eye fundus evaluation did not reveal pathological changes.

Laboratory analyzes did not reveal any changes. After the diagnosis was made, the multiple chalazia excision was performed under general anesthesia and the following postoperative treatment was recommended: general (Azithromycin 150 mg / 12 hrs., Dexamethasone 2 mg / 12 hrs.), topic (Tobradex ointment, artificial tears) and eyelashes-palpebral massage with Betadina 5%, Blefagel, with favorable post-operative evolution. From the extracted collection is sent for histopathological and bacteriological examination (fig.2, 3), which reveals a lymphogranulomatosis inflammation and does not isolate the microbial flora.

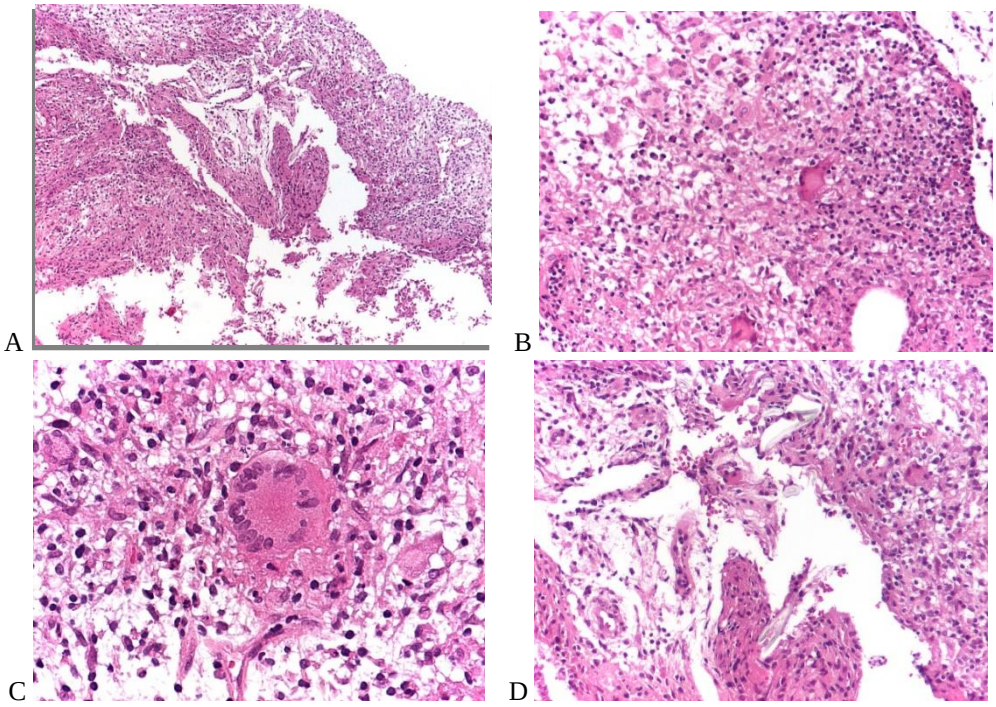

Fig. 2. Histopathological examination (lymph granulomatous inflammation)
A. Aggregate, polymorphic inflammatory granulation tissue, HE, x 4. B. Multinucleated giant cells with rare epitheliomas and polymorphic inflammation, HE, x 10
C. Multinucleated giant cells, HE, x 20 D. giant multinuclear cells on hair, HE, x 10.

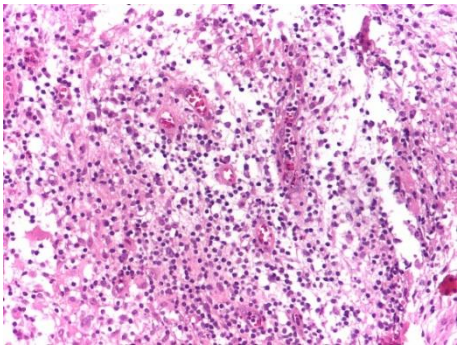

Fig. 3. Histopathological examination, granulation tissue, detail, HE, x 10

At the 1, 2-week control, was observed the absence of pseudo tumoral formations, the reduction of the congestion of the palpebral, only a slight thickening of the palpebral margin (fig.4). Prognosis is favorable, but it requires rigorous hygiene and long-term follow-up.

Fig. 4. Clinical appearance 2 weeks post-operatively

DISCUSSION

Chalazion is a chronic inflammatory granuloma of the Meibomian gland. The major effects are cosmetic deformation with variable discomfort. Microscopy reveals lipogranulomatosis reaction caused by released fat globules, histiocytes surrounded by multinucleated giant cells of epithelial and interstitial neutrophils, lymphocytes, and plasma cells (3, 4, 5, 6). Clinically presence of a pseudo tumoral form at the palpebral level must exclude inflammation of the meibomian glands, idiopathic facial granuloma, palpebral carcinoma and hordeleum etc. It is often associated with rosacea acne, especially in the child, but the diagnosis is difficult to put. Studies show that 58% of patients with rosacea have eye-eye symptoms. Rosacea tends to start in childhood as a common rash, often in response to stress. A diagnosis beyond this initial stage of rosacea is unusual in the pediatric population. If a child is identified with an intermediate stage of rosacea, consisting of papules and pustules, an eye examination should be performed to exclude ocular manifestations (4, 5, 6).

Ophthalmologists should consider acne rosacea as a potential diagnostic for any child who has any combination of meibomian disease, chronic blepharitis, chalazion recurrent and chronic symptoms of photophobia, eye irritation and redness that does not respond to routine medical treatment. Centikaya *et al.* maintain that patients respond well to generalized treatment with erythromycin or doxycycline (13). Another diagnosis we should think of when experiencing recurrent, multiple salicylates ,is hyperimmunoglobulin E syndrome (Job's syndrome). It is a rare form of immunodeficiency characterized by skin, pulmonary, and ocular palpebral abscesses (multiple, giant chalazia). Characteristic is the presence of an increased level of immunoglobulin E (3). It is rarely found in avitaminosis cases or may be induced by a viral infection (14,15). Excluding reddish acne in our case is quite difficult. We must also keep in mind the mother's heredal collateral history, as well as the good response to the general specific antibiotics that the patient received.

Sebaceous carcinoma is notorious for masquerading clinically as other benign

lesions such as chalazion (16, 17). In one study, it was the most commonly missed malignancy (1.1%) among 1,060 cases diagnosed clinically as chalazion (18). Other studies have found the rate of misdiagnosis of sebaceous carcinoma as chalazion to be 25.6% and 20% (19)

Therapeutic conduct should be appropriate to the case and should also consider the causes of recurrent palpebral inflammation. Studies recommend both local excisional therapy and intralesional anti-inflammatory injection, the results being similar (10, 11, 12). In our case, the appropriate initial treatment would have led to a limitation of the extent of inflammation and implicitly avoidance of local complications due to lack of treatment or inadequate treatment. Fortunately, the postoperative evolution was favorable, and the prognosis is good, but requires rigorous local hygiene and adequate follow-up. The case was difficult to manage on the one hand because of the severity of injuries due to an inadequate treatment, the content of granular tablets Sinerdol has no ophthalmic use (chemical burns), on the other hand empirically treatment applied could cause further complications (thermal burns).

CONCLUSIONS

Ophthalmologists should consider acne rosacea as a potential diagnostic for any child who has any combination of Meibomian disease, chronic blepharitis, recurrent chalazion and chronic symptoms of photophobia, eye irritation and redness that does not respond to routine medical treatment. Appropriate treatment initiated from onset would have limited the extension of the chalazia; with the possibility of avoiding the surgical treatment and the risk involved in general anesthesia. Reddish acne does not have standardized diagnostic criteria for the child, which is why the patient should be followed in the long run by a multidisciplinary team of ophthalmologist, dermatologist and pediatrician.

TRANSABDOMINAL CERCLAGE CAN IMPROVE THE PROGNOSIS OF PREMATUR DELIVERY?

Transabdominal cerclage (TAC) tends to be the best form of treatment aiming to improve the obstetric prognosis for patients with cervical incompetence as a result of a large conization, but also for patients who face cervical cerclage after radical trachelectomy. A retrospective review of 11 cases in which TAC was performed showed that five patients with an ultra-short cervix continued their pregnancies until the time for the scheduled caesarean section. A Teflon thread is inserted into the avascular space between the uterine vessels and uterine muscle, and it's tied firmly at the front side of the uterus. That can be kept for 2 years utmost, but if no abnormal findings are detected at the time of cesarean section, this term could most likely be extended. Complications result from the use of non-absorbable thread. In order to avoid two additional laparotomies, a laparoscopic surgery might be an alternative (Ishioka S, Kim M, Mizugaki Y, Kon S, Isoyama K, Mizuuchi M, Morishita M, Baba T, Sekiya T, Saito T. Transabdominal cerclage (TAC) for patients with ultra-short uterine cervix after uterine cervix surgery and its impact on pregnancy. *J Obstet Gynaecol Res*. 2017, doi: 10.1111/jog.13487).

NON-INVASIVE EVALUATION OF LIVER FIBROSIS IN CHRONIC HEPATITIS C (Abstract): Chronic hepatitis C (CHC) is a major public health concern, with around 180 million individuals affected worldwide. Liver fibrosis and its end-point cirrhosis are the main causes of morbidity and mortality in patients with CHC. Liver biopsy (LB) has traditionally been considered the „gold standard" for pre-treatment evaluation of liver fibrossis in patients with CHC. However, LB is an invasive procedure with several shortcomings (intra- and interobserver variability, sampling errors, expensive) and the risk of rare but potentially life-threatening complications (biliary peritonitis, hemo-peritoneum, and death in 1/10,000). The aforementioned shortcomings of LB have led to development of several non-invasive methods for the assessment of liver fibrosis in CHC. Among the non-invasive methods, Fibrotest and Fibroscan are the most widely used in our country and offer a viable alternative to LB for pre-treatment assessment of liver fibrosis in patients with CHC. This review aims to discuss the advantages and usefulness of non-invasive methods of liver fibrosis in CHC. **Key words:** CHRONIC HEPATITIS C, LIVER FIBROSIS, LIVER BIOPSY, FIBROTEST, FIBROSCAN.

Chronic hepatitis C (CHC) is a major public health problem and a leading cause of cirrhosis, end stage liver disease and hepatocellular carcinoma (1). An estimated 180 millions people are affected worldwide, and the health burden associated with CHC is expected to increase during the next 20 years (2). Liver fibrosis and its end-point cirrhosis are the main causes of morbidity and mortality in patients with CHC and therefore, the assessment of fibrosis is an important issue in the management of these patients (3). Liver biopsy (LB) is still regarded as the „gold standard" for evaluating the liver fibrosis in spite of its several shortcomings: 1) *inter-observer and intra-observer variability of histopathologic interpretation*: there are significant differences between pathologist's interpretation of the biopsies (4); 2) *sampling errors:* inadequate biopsy specimens size will make histopathological examination irrelevant and miss the diagnosis of cirrhosis in more than 25% of patients (5); 3) *complications* may be minor (anxiety, pain, transient hypotension) or major, including bleeding (intra-hepatic, intra-peritoneal), bile-peritonitis, puncture of pleura, colon,

and kidney, with the mortality rate ranging from 0.01% to 0.1% (6); 4) *other limitations:* high costs, variable accessibility, low acceptance by patients and, a method which provides only a static measure of fibrosis and therefore not suitable for repeated evaluation. The above mentioned shortcomings of LB have led to development of non-invasive methods for the assessment of liver fibrosis in CHC; these methods range from serum marker assays to advanced imaging techniques. This review aims to discuss the advantages and usefulness of non-invasive methods of liver fibrosis in CHC.

SERUM MARKERS OF LIVER FIBROSIS

The serum markers of liver fibrosis are commonly divided in two groups:1) *direct serum markers* which are directly linked to the modification in extra-cellular matrix turnover produced by hepatic stellate cells during the process of fibrogenesis in the liver; 2) *indirect serum markers* which reflect alterations in hepatic function.

The "direct markers" include glycoproteins (hyaluronate, laminin, YKL-40), collagen family (procollagen III, type IV collagen), collagenases and their inhibitors (matrix metalloproteases, tissue inhibitory metalloprotease-1). The "indirect markers" are biochemical parameters determined in routine blood tests (7). Several combinations of "direct" and "indirect" serum markers have been proposed and validated in CHC (table 1).

TABLE I

Combinations of serum markers for non-invasive diagnosis of liver fibrosis

Marker	Description
APRI	AST to platelets ratio index
Fibrotest	Age, gender, alpha-2-macroglobulin, γGT, haptoglobin, apolipoprotein A1, total bilirubin
Lok index	AST/ALT ratio, platelets, INR
Forns index	Age, BMI, γGT, cholesterol
Fibroindex	AST, platelets, gamma-globulins
Fib-4	Age, AST, ALT, platelets
Hepascore	Bilirubin, γGT, hyaluronic acid, alpha-2-macroglobulin, age, sex
Fibrometer	Age, AST, platelets, hyaluronan, INR, alpha-2-macroglobulin, urea
Fibrospect	Alpha-2-macroglobulin, hyaluronan, TIMP1
ELF*	Age, hyaluronic acid, type III procollagen, TIMP1
FIP*	Age, past alcohol intake, cholesterol, AST, HOMA-IR
Virahep-C	Age, AST, platelets, alkaline phosphatase
GUCI*	AST, INR, platelets

* ELF: European liver fibrosis group; FIP: Fibrosis Probability Index;
GUCI: Göteborg University Cirrhosis Index

Fibrotest and APRI are the most widely used before making a decision on antiviral therapy in patients with CHC. APRI (AST/platelets ratio) is a simple, chip, and readily available in the clinical practice, with an accuracy between 60% and 82% for significant fibrosis (8). Fibrotest is a patented test, with the accuracy reported ranges from 70-85% (8). To improve the performance of Fibrotest for the assessment of fibrosis in CHC, its combination with Fibroscan has been suggested. With such combination one study reported areas under the receiver curve (ROC) for 0.88 $\geq$ F2 (stage in the Metavir scoring system), 0.95 for $\geq$ F3 and 0.95 for F4 (9).

There are some limitations of serum markers; none is liver specific, and have poor performance in diagnosis of intermediate stages of liver fibrosis. However, it is important to note that the performance of each non-invasive marker is evaluated against LB which is an imperfect "gold standard", and the apparent failure of non-invasive markers to make accurate distinction between different stages of intermediate fibrosis could be the consequence of misclassification from LB (10). Poynard et al (11) have assessed the accuracy of Fibrotest, Fibroscan and biopsy using methods without gold standard in patients with CHC and found that both Fibrotest and Fibroscan to be accurate for the diagnosis of advanced fibrosis and cirrhosis in such patients.

IMAGING TECHNIQUES

Transient elastography **(**Fibroscan®, Echosens, Paris, France) measures the liver stiffness in a volume that is at least 100 times greater than a standard LB sample and therefore, may be more representative of the entire liver. Fibroscan is composed of an ultrasound transducer probe mounted on the axis of a vibrator; vibration is transmitted to induce an elastic shear wave that propagates through the liver. Pulse-echo ultrasound acquisition is used to measure the velocity of the shear wave, which is directly related to the liver stiffness: the stiffer the liver, the faster the shear wave propagates. Results are expressed in kilo-Pascals (kPa), and the values range from 2.5 to 75 kPa, with normal values less than 5.5 kPa. According to several studies, a cutoff value of 7.2 to 8.7 kPa defines significant fibrosis, and cirrhosis is diagnosed by cutoff value of 12.5 to 14.5 kPa (12). Several studies have confirmed that Fibroscan can accurately assess liver fibrosis in patients with CHC (13); it is an excellent method for the diagnosis of cirrhosis (F4) (14), and this is the reason that Fibroscan is gaining popularity worldwide to confirm or to rule out cirrhosis in patients with CHC.

Fibroscan has several advantages: it is painless, quick (less than 5 minutes), with results immediately available, inexpensive, and easy to be performed in the outpatient clinic and at the bedside. Fibroscan measurement failure is due to obesity, narrowed intercostal space, and limited operator experience.

Acoustic Radiation Force Impulse (ARFI) imaging combines conventional ultrasonography of the liver with evaluation of local liver stiffness. Results are expressed in meter/sec and the method allows operator to avoid large blood vessels or ribs. Recent studies have shown excellent diagnostic accuracy to identify significant fibrosis and cirrhosis and in some of them ARFI measurements were highly correlated with those of Fibroscan (15).

Magnetic resonance elastography (16) directly visualizes and measures acoustic shear wave's propagation through the liver;

the advantages of this method include the possibility to be used in patients with obesity or ascites. The main shortcoming of MR-elastography is its high cost which precludes its use in clinical practice for hepatic fibrosis screening and therefore, it remains as a research tool.

CONCLUSIONS

Unfortunately, so far no single ideal method (high sensitivity and specificity in identifying different stages of fibrosis, safe, with no risk for the patient, inexpensive, readily available, reproducible) exists for liver fibrosis. Therefore, we should choose the method with enough diagnostic accuracy and no risk for the patient with CHC. It is obvious that LB has several shortcomings, and that non-invasive methods offer viable alternatives to be used for staging of fibrosis in patients with CHC who are candidates for antiviral therapy. The rate of adoption of non-invasive tests by hepatologists differs from country to country. In France, a survey of 546 hepatologists revealed that 81% of them used the non-invasive methods (17). Our team has been the first in Romania which tried and succeeded to break the monopoly that LB has maintained on the evaluation of liver fibrosis in patients with CHC. Thus, Fibroscan and Fibrotest are used as first-line staging of fibrosis before making a decision on antiviral therapy. Once direct-acting antiviral therapy becomes available in many countries, and the allocation system will be based on „medical need" (therapy for the sickest patients), non-invasive assessment tests with highest accuracy for severe fibrosis/cirrhosis (i.e., Fibroscan) will play an important role. Therefore, it is surprising that many experts in the field of hepatology, still recommend LB for evaluation of fibrosis in patients with CHC. We believe that the time has arrived for moving forward to non-invasivity, no risk for patients, and high diagnosis accuracy in evaluating advanced stages of hepatic fibrosis in patients with CHC candidates for antiviral therapy.

ANTERIOR CERVICAL SPINE HYPEROSTOSIS - A RARE CAUSE OF DIFFICULT INTUBATION ÎN EMERGENCY (Abstract): DISH (Diffuse idiopathic skeletal hyperostosis) of cervical spine is a rare condition which causes dysphagia in 23% of cases and occasionally dyspnea. The authors report the case of a 74 years old male, known with progressive dysphagia and recurrent episodes of dysphonia and dyspnea, who suffered a sudden episode of respiratory distress that need finaly tracheotomy after ineffective attempts of orotracheal intubation. **Key words** OLLA, OROTRACHEAL INTUBATION, ENTEZOPATHY

DISH (hiperostoza scheletică difuză idiopatică), este o afecțiune descrisă de Forestier şi Rotes Querol în 1950, caracterizată prin rigidizarea tendoanelor şi ligamentelor prin calcifiere şi osificare difuză la nivel spinal şi extraspinal (umăr, cot, mână, şold, genunchi, plantă) (1, 2).

Scheletul axial este frecvent implicat, osificarea ligamentului cervical anterior este frecventă şi discontinuă, în special localizată la nivelul segmentului toraco-lombar. Localizarea cervicala este rară (3, 4).

PREZENTARE DE CAZ

Pacientul D. R., în vârsta de 74 de ani, cunoscut cu disfagie progresivă de 2 ani, disfonie şi dispnee intermitentă (aflat în investigații pentru o eventuală patologie malignă farino-laringiană), se prezintă la camera de gardă cu un episod brusc de insuficiență respiratorie acută. Întrucât tentativele de intubație orotraheală au eşuat, s-a solicitat serviciul O.R.L. şi s-a efectuat traheotomia de urgență.

Din antecedentele patologice s-a reținut diabetul zaharat (DZ) tip 2, aflat sub tratament, iar analizele de laborator au evidențiat o trombocitopenie severă (12000 trombocite/mm^3, la internare, apoi 20000 după 3 zile de administrare de dexametazonă), care nu s-a corectat pe parcursul internării.

Examenul clinic a evidențiat bombarea peretelui posterior al oro şi hipofaringelui, dar laringele nu s-a putut examina indirect inițial (laringoscopie indirectă); ulterior, fibroscopia a arătat un edem important al vestibulului laringian probabil datorat tentativelor de intubație, fără afectarea corzilor vocale, cu moderată stază salivară în sinusurile piriforme (excluzându-se astfel patologia tumorală faringiană şi laringiană).

Radiologia a tranşat diagnosticul, con-

form criteriilor lui Resnick (6): 1) punți osoase antero-laterale la cel puțin 4 corpuri vertebrale, 2) neafectarea aparentă a spațiilor intervertebrale, 3) absența ankilozei apofizare şi a sclerozei sacroiliace.

Examenul imagistic (RMN) a evidențiat hiperostoză voluminoasă, compresivă la nivelul C2-C6 având aspectul unei formațiuni cu aspect fuziform pe secțiunile sagitale, situată anterior de ligamentul vertebral ventral şi posterior de muşchiul lung al gâtului (pe secțiunile axiale) pe care îl deplasează lateral, cu efect de masă la nivelul hipofaringelui şi laringelui, în hipersemnal T2 şi izosemnal T1 fat sat după administrarea substanței de contrast (gadolinium) cu corpii vertebrali adiacenți (fig. 1, 2).

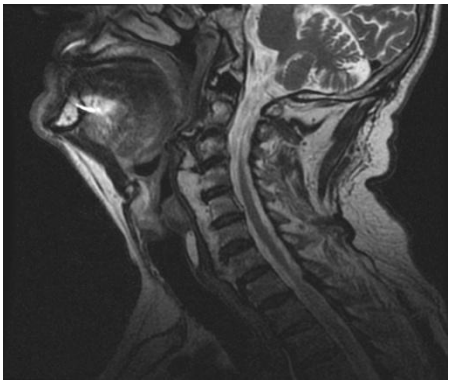

Fig. 1. Secțiune sagitală –IRM

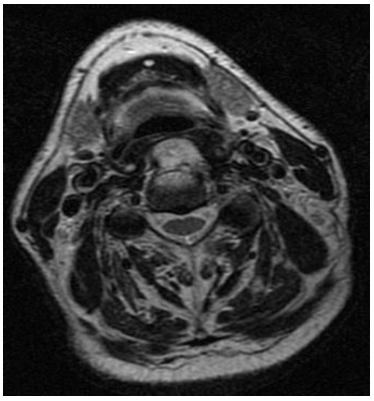

Fig. 2. Secțiune axială - IRM

Datorită trombocitopeniei, pacientul a fost ulterior transferat într-un serviciu de hematologie pentru investigații şi tratament de specialitate, iar riscul de insuficiență respiratorie fiind important, pacientul a rămas cu canula traheală; tarele sale (DZ şi trombocitopenia) nu au permis o abordare chirurgicală a hiperostozei cervicale.

DISCUȚII

DISH este o spondiloartropatie cunoscută de asemenea sub numele de boala Forestier, hiperostoza ankilozantă senilă (5).

Este o boală neinflamatorie manifestată în principal prin osificarea difuză şi calcifierea tendoanelor, ligamentelor, fasciilor atât a scheletului axial cât şi articulațiilor periferice, ceea ce i-a determinat pe cercetători să utilizeze termenul DISH (2,3).

Această boală are o predilecție pentru bărbați (65%) şi este frecventă la pacienții cu vârsta peste 50 ani, cu o prevalență de aproximativ 15-20% din populația generală în vârstă (6,7). Prevalența DISH în populația generală variază foarte mult în funcție de locația de studiu. A fost citată o rată de prevalență de până la 27,3% la bărbați şi 12,8% la femei (8). Frecvența internațională arată că aproximativ 0,16% din caucazieni suferă de această boală (9). Un alt studiu de prevalență DISH a populației de negri din Africa de Sud cu vârsta de peste 40 de ani a raportat ca prevalenta DISH a fost de 3,9% (3,8% bărbați şi 4,2% femei). Prevalența a crescut odată cu vârsta. Prevalența DZ la pacienții cu DISH a fost de 52,4% (10). Coloana vertebrală toracică este afectată frecvent (95%), urmată de afectarea coloanei lombare şi cervicale (4,11). DISH determina osificarea ligamentului longitudinal anterior (OLLA), fiind raportat la 25% bărbați şi 15% femei, din populația generală cu vârsta peste 50 ani (7).

În populația din Asia, în special în rândul populației japoneze, osificarea ligamentului longitudinal posterior (OLLP) are prevalența de 1,9-4,3% (12). OLLP şi DISH apar frecvent împreună, 50% din cazurile de DISH fiind raportate în asociere cu un anumit grad de OLLP (13).

Etiologia DISH este încă un mister, fiind sugerate mai multe teorii, motiv pentru care este greu de a identifica factorii de risc. Lista cu posibilii factori de risc include medicamente specifice - retinoizi, isotretinoid (Accutane-R), similare cu vitamina A, ce pot creşte riscul de DISH, dar încă nu este clar dacă un aport ridicat de vitamina A creşte riscul de DISH (14,15). Un alt studiu făcut pe animale a arătat că nivelurile plasmatice mari de vitamina A cresc riscul de DISH. Pe model uman astfel de studii nu au fost găsite în literatura de specialitate (17). Un articol de revizuire recenta a bolii Forestier realizat de Sarzi-Puttini şi Atzeni arată o prevalență mai mare a DISH in cazul pacienților cu obezitate şi hiperuricemie (18) dar indicele de masa corporala luat singur nu este considerat factor de risc (16,18). Vezyroglou a arătat că pacienții cu DZ, boală coronariană, hipertensiune arterială, hiperuricemie (gută), dislipidemie sunt mai susceptibili de a dezvolta DISH (16).

Manifestările clinice sunt variabile. Unii subiecți sunt complet asimptomatici, în timp ce alții se plâng de cervicalgii, rigiditate şi simptome secundare compresiunii excrescentelor osoase asupra structurilor vecine. Compresiunea faringo-esofagiană şi traheala se manifestă prin disfagie, dispnee, stridor, pneumonie de aspirație, mielopatie, apnee in somn (19, 20). Incidenta disfagiei raportată la pacienți cu DISH este cuprinsă în intervalul 0,2-28%. Dispneea este mai comună (21). Disfagia la pacienți cu DISH cu localizare cervicală apare ca urmare a compresiunii de diferite grade la nivelul esofagului, afectarea mobilității epiglotice şi a funcției sfincteriene a laringelui, distorsiuni ale cartilajelor laringiene (21). DISH predispune la complicații cum ar fi leziuni iatrogene ale mucoasei laringiene şi esofagiene în timpul procedurilor endoscopice şi intubare orotraheală (19).

Pentru confirmarea diagnosticului de DISH de obicei este suficientă radiografia convențională, radiografia cu bariu. Videofluoroscopia dinamică ar trebui să fie rezervată pentru a demonstra relația exactă a modificărilor la nivelul coloanei cervicale cu funcția de deglutiției la acei pacienți care se confruntă cu disfagia (22). Radiografia cu bariu şi videofluoroscopia va confirma comprimarea esofagiana şi obstrucția în ceea ce priveşte prezența osteofitelor mari anterior. Endoscopia la aceşti pacienți prezintă un risc de perforare, dar este necesară pentru a exclude alte cauze intrinseci ale disfagiei cum ar fi stricturi esofagiene, esofagite, tulburări de motilitate, tumori, candidoze (23).

Tomografia computerizată (T.C.) şi investigațiile prin rezonanță magnetică nucleară (R.M.N.) la nivelul coloanei cervicale pot fi folosite pentru o mai buna detectare a osteofitelor (mărime, formă), în raport cu faringele, laringele, esofagul, sau a complicațiilor DISH (stenoza canalului vertebral, mielomalacia) precum şi prezența OLLP asociat în 50% din cazuri cu DISH (24).

În prezent diagnosticul de DISH este bazat pe criterii de clasificare, care necesită prezența de osteofite cu dispoziție anterolaterală la nivelul coloanei vertebrale. Criteriile de clasificare stabilite de Resnick şi Niwayama implică cel puțin 4 vertebre învecinate, conservarea spațiului de disc

intervertebral, păstrarea integrității discului, absența ostesclerozei marginale, lipsa eroziunilor şi sclerozei în articulația sacroiliacă (25). Utsinger a redus pragul de implicare a coloanei vertebrale la 3 corpuri vertebrale învecinate, dar a adăugat prezența entezopatiei periferice pentru diagnosticul de DISH (4). Julkunen a sugerat că implicarea a 2 corpuri vertebrale în cel puțin 2 locuri ale coloanei vertebrale sa fie caracteristice pentru DISH (26). Modificările coloanei în segmentul cervical, în special C3-C4, afectează funcțiile laringelui inclusiv cea respiratorie (22), în timp ce dezvoltarea hiperostozei în segmentele C5-C7, poate produce spasmul sfincterului esofagian superior şi compresiune esofagiană (23,27).

CONCLUZII

DISH este o afecțiune comună trecută cu vederea la persoanele vârstnice. Etiologia DISH nu a fost definită dar există asociații cu obezitatea, diabetul, hipercolesterolemia şi guta. DISH cu afectarea coloanei cervicale este o cauza mai puțin frecventă de disfagie însă poate fi trecută cu vederea, deoarece disfagia este des întâlnita la persoanele vârstnice. Diagnosticul de DISH se stabileşte de obicei în faza ireversibilă, pe deplin dezvoltată a osteofitelor, când apar complicațiile şi riscul de perforare în timpul endoscopiei şi a intubației orotraheală. Intervenția chirurgicală (osteofitectomie) poate fi luată în considerare, dar datorită asocierii factorilor de risc (vârsta, diabetul, HTA) se preferă tratamentul conservator, care include medicamente antiinflamatorii nesteroidiene, corticosteroizi, relaxante musculare şi modificarea dietei.

Cunoaşterea DISH cu localizare cervicală înainte de intubația orotraheală poate indica dificultăți ce pot impune măsuri aşazise invazive de restabilire a funcției respiratorii. Deşi rar, DISH cu afectare cervicală trebuie suspicionat la orice pacient cu disfagie progresivă şi dispnee, disfonie intermitentă şi/sau sindrom de apnee în somn, iar consultul interdisciplinar (O.R.L.) şi investigațiile radiologice trebuie efectuate pentru determinarea diagnosticului şi a eventualității unei intubații dificile.

DESCRIPTIVE ASSESSMENTS OF A SERIES OF RHEUMATOID ARTHRITIS PATIENTS ADMITTED TO REHABILITATION TREATMENT BETWEEN 2008 AND 2010 (Abstract): **Aim:** To assess some demographic features in a series of 741 rheumatoid arthritis patients admitted to the Clinic Hospital of Rehabilitation at Iasi in different stages of disease in order to select the most adequate rehabilitation teratment. **Material and methods**: Data were collected from patients' records, hospital statistical reports, and then processed and interpreted using EPI/INFO and MS Excel. **Results**. Sex distribution revealed that the disease was more common in females (male/female ratio 0.2). The prevalence was higher after the age of 40, from 15.4% to 33.8% between 51 and 60, and 40.2% after 61. The most important comorbidities were related to osteoporosis (48.9%), ischemic cardiopathy and essential arterial hypertension (40.1%), impaired glucose tolerance and diabetes mellitus (36.9%), viral hepatitis B and C (24.02% of all cases). **Conclusions**. In selecting the most adequate rehabilitation treatment (drug therapy, kinetotherapy, and physical therapy) patient's age, and his various associated diseases have to be considered. **Key words:** RHEUMATOID ARTHRITIS, PREVALENCE, COMORBIDITIES, REHABILITATION

Poliartrita reumatoidă este o boală rară la bărbaţi sub 30 de ani, dar incidenţa ei creşte şi atinge vârful după 60 de ani. La femei, prevalenţa bolii creşte constant începând cu jumătatea celei de a 3-a decade atingând un nivel constant şi ridicat între 45 şi 75 de ani. Uneori debutează postpartum, iar relaţia cu traumatisme fizice sau stress psihologic este uneori posibilă (1, 2, 3).

Dacă prognosticul vital este rar compromis după o perioadă obişnuit de lungă de boală, cel funcţional devine, cu fiecare zi, tot mai precar, iar cheltuielile financiare ocupă un loc important, atât în bugetul familial, cât şi în cel social (4, 5). În acest sens, sunt de menţionat tratamentul îndelungat, cu un cost ridicat, precum şi numărul de zile de spitalizare, incapacitatea de muncă. La toate acestea se adaugă costul investigaţiilor paraclinice, precum şi tratamentul recuperator, în vederea ameliorării inserţiei sociale (6, 7, 8). Concomitent se

are în vedere ameliorarea vieţii cotidiene şi realizarea unei inserţii socio-economice optime cu efecte favorabile pentru bolnav, familie şi societate (9, 10, 11, 12).

Studiul de faţă are ca scop evaluarea unor caracteristici demografice ale lotului de pacienţi cu poliartrită reumatoidă, unele aspecte ale factorilor de risc implicaţi în etiologia bolii, ale investigaţiilor paraclinice, în legătură cu instituirea şi eficienţa exerciţiului fizic la aceştia, ca metodă terapeutică.

MATERIAL ŞI METODE

Studiul clinic de tip descriptiv a fost efectuat pe un lot de 741 pacienţi diagnosticaţi cu poliartrită reumatoidă, aflaţi în variate stadii de evoluţie şi care au fost internaţi şi asistaţi terapeutic şi evolutiv în Spitalul Clinic de Recuperare, Iaşi, în perioada 2008-2010. Acest lot a cuprins şi reinternările, deci, studiul se referă la prevalenţa bolii.

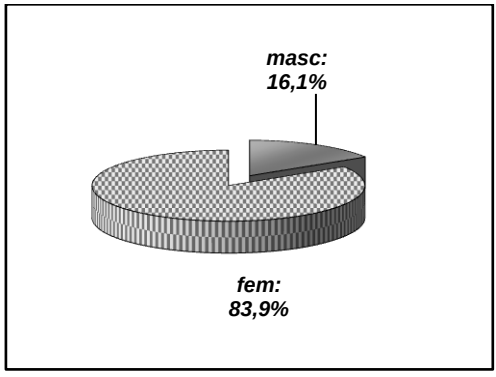
Culegerea informaţiilor s-a realizat prin evaluarea foilor de observaţie ale pacienţilor, precum şi a raportărilor statistice ale Spitalului Clinic de Recuperare, Iaşi. Pentru prelucrarea şi interpretarea datelor acumulate s-au folosit programele computerizate MS Excel, EPI/INFO, iar metodele biostatistice au inclus calcularea prevalenţei globale, specifice, a probabilităţii, regresiei liniare şi tendinţei.

REZULTATE ŞI DISCUŢII

1. Structura lotului

Repartiţia pe sexe a evidenţiat predominanţa femeilor, atât pentru fiecare an, cât şi cumulativ pentru cei 3 ani luaţi în studiu, cu un raport masculin / feminin de 0,2. Această valoare obţinută de noi este în concordanţă cu rezultatele altor studii privind predominanţa poliartritei reumatoide la sexul feminin, cu o diferenţă puternic semnificativă ($p<0,001$). *Repartiţia pe medii de reşedinţă a pacienţilor* a fost în favoarea celui urban, însă cu diferenţe statistic nesemnificative, în toţi anii luaţi în studiu ($p>0,05$). Această constatare se regăseşte în datele din literatura de specialitate, publicate în străinătate, cât şi în România (fig. 1).

Explicaţia ar consta nu în faptul că, în mediul rural, ar exista un cumul de factori de protecţie şi deci o lipsă a factorilor de risc pentru poliartrita reumatoidă, cât, mai degrabă, o deficienţă a adresabilităţii către medic a pacienţilor din rural, comparativ cu cei din mediul urban, aceştia din urmă având şi un acces mai facil la cabinete, spitale şi investigaţii de specialitate.



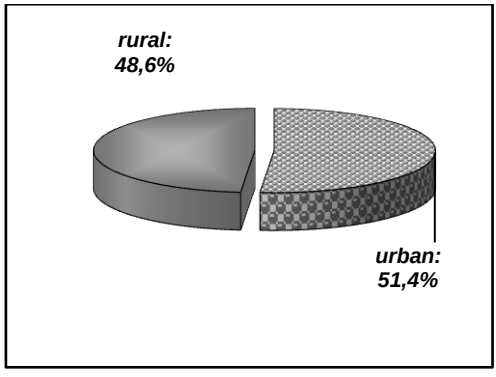


Fig. 1. Repartiţia pe sexe şi medii de reşedinţă a pacienţilor studiaţi

Repartiţia pe grupe de vârstă. Poliartrita reumatoidă a fost înregistrată la toate grupele de vârstă: 2,4% din cazuri au fost semnalate până la vârsta de 30 de ani; 8,2% pentru 31-40, remarcându-se o creştere a prevalenţei cazurilor după vârsta de 41 ani, de 15,4% până la 50, 33,8% între 51 şi 60 şi 40,2% cazuri cu vârsta peste 61 ani. Date similare au fost menţionate şi în alte cercetări (2, 3, 6), de unde rezultă necesitatea preocupării pentru depistarea precoce a poliartritei reumatoide, la toate vârstele, cu deosebire pentru femei şi grupele de vârstă de peste 40 de ani (fig. 2).

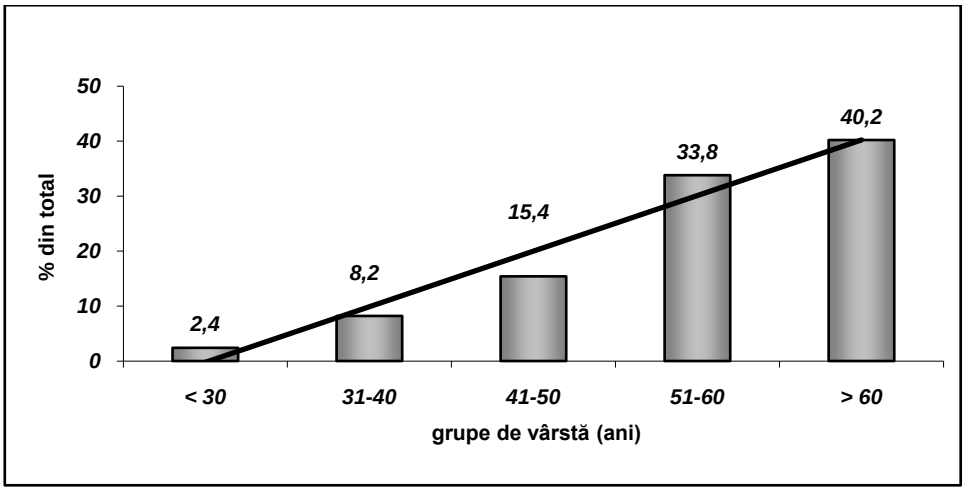

Fig. 2. Repartiţia pe grupe de vârstă

Calcularea regresiei liniare arată faptul că prevalenţa cazurilor de poliartrită reumatoidă are o prevalenţă cu tendinţă crescătoare spre grupele de vârstă de peste 40 ani. Această constatare am întâlnit-o, de asemenea, în studiile altor autori publicate în literatură (5, 8, 9).

O altă modalitate de a descrie lotul de studiu este distribuţia pacienţilor cu poliartrită reumatoidă pe *categorii ocupaţionale* active sau pasive. Se observă faptul că 298 (40,2%, adică aproape jumătate din lotul studiat) dintre bolnavi aparţin grupei de vârstă de 61 ani şi peste, persoane cu o activitate fizică mai redusă, posibil, din cauza pensionării, dar şi a prezenţei comorbidităţilor. Acest fapt poate avea influenţă asupra terapiei, în special kinetoterapiei şi recuperării.

2. Consideraţii asupra diagnosticului şi comorbidităţilor

Structura lotului studiat în relaţie cu diagnosticul. Din cei 741 pacienţi luaţi în studiu, în perioada 2008-2010, 635 (85,7%) au prezentat diagnosticul de „*Alte artrite reumatoide seropozitive cu localizări multiple*" (codul OMS: M05.80), iar 106 (14,3%) dintre ei au primit diagnosticul de „*Artrită reumatoidă seronegativă, cu localizări multiple*" (cod OMS: M06.00). Astfel, am subîmpărţit lotul de studiu în două grupuri, denumindu-le conform codurilor OMS: grupul „M05.80" şi grupul „M06.00", pe care le-am analizat, luând în consideraţie variabilele statistice sex, medii de reşedinţă şi grupe de vârstă.

Din analiza de statistică descriptivă, se constată că prevalenţa specifică atinge cea mai mare valoare pentru grupele de vârstă

de peste 60 ani, cu predominanţa sexului feminin, iar distribuţia pe medii de reşedinţă (urban/rural) nu a prezentat diferenţe statistic semnificative (tab. I, II).

TABELUL I

Distribuţia pe grupe de vârstă, sexe şi medii de reşedinţă a cazurilor cu diagnosticul de „*Alte artrite reumatoide seropozitive cu localizări multiple*”

Grupa de vârstă (ani)																			
< 30				**31-40**				**41-50**				**51-60**				**> 60**			
Fem		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*	
R	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*
3	9	3	1	24	22	5	2	28	47	14	5	72	116	14	14	86	93	45	42
12		*4*		*36*		*7*		*75*		*19*		*188*		*28*		*179*		*87*	
Total 16				***43***				***94***				***216***				***266***			
Total general = 635 cazuri																			

TABELUL II

Distribuţia pe grupe de vârstă, sexe şi medii de reşedinţă a cazurilor cu diagnosticul de „*Artrită reumatoidă seronegativă, cu localizări multiple*”

Grupa de vârstă (ani)																			
< 30				**31-40**				**41-50**				**51-60**				**> 60**			
Fem		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*		*Fem*		*Masc*	
R	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*	*R*	*U*
0	0	2	1	4	1	2	0	5	10	1	2	7	22	4	1	25	12	3	4
0		*3*		*5*		*2*		*15*		*3*		*29*		*5*		*37*		*7*	
Total = 3				***7***				***18***				***34***				***44***			
Total general = 106 cazuri																			

Se observă că, în ambele grupuri de diagnostic, se păstrează ponderea grupelor de vârstă, cu diferenţe statistic nesemnificative. Date descriptive similare au fost publicate şi de alţi autori, în concluziile studiilor referitoare la poliartrita reumatoidă (1, 2, 3, 7, 9). Aceste constatări sunt utile în alegerea terapiei recuperatorii şi a exerciţiilor fizice, la pacienţii cu poliartrită reumatoidă, asistaţi în clinica noastră.

*Observaţii privind distribuţia comorbidităţilor***.** În perioada luată în studiu, cele mai importante patologii asociate la cazurile cu poliartrită reumatoidă au interesat sistemul osteoarticular (osteoporoză în 48,9% din total cazuri), circulator şi cardiac (cardiopatie ischemică şi hipertensiune arterială esenţială – 40,1%), pancreasul (scăderea toleranţei la glucoză şi diabet zaharat – 36,9%), ficatul (hepatită virală B şi C – 24,02%) atât separat, cât şi în contextul patogenezei autoimune a bolii (fig. 3). Datele obţinute, referitoare la patologiile asociate întâlnite la pacienţii cu poliartrită reumatoidă, sunt în acord cu cele concluzionate de alţi cercetători (1, 2, 5, 6).

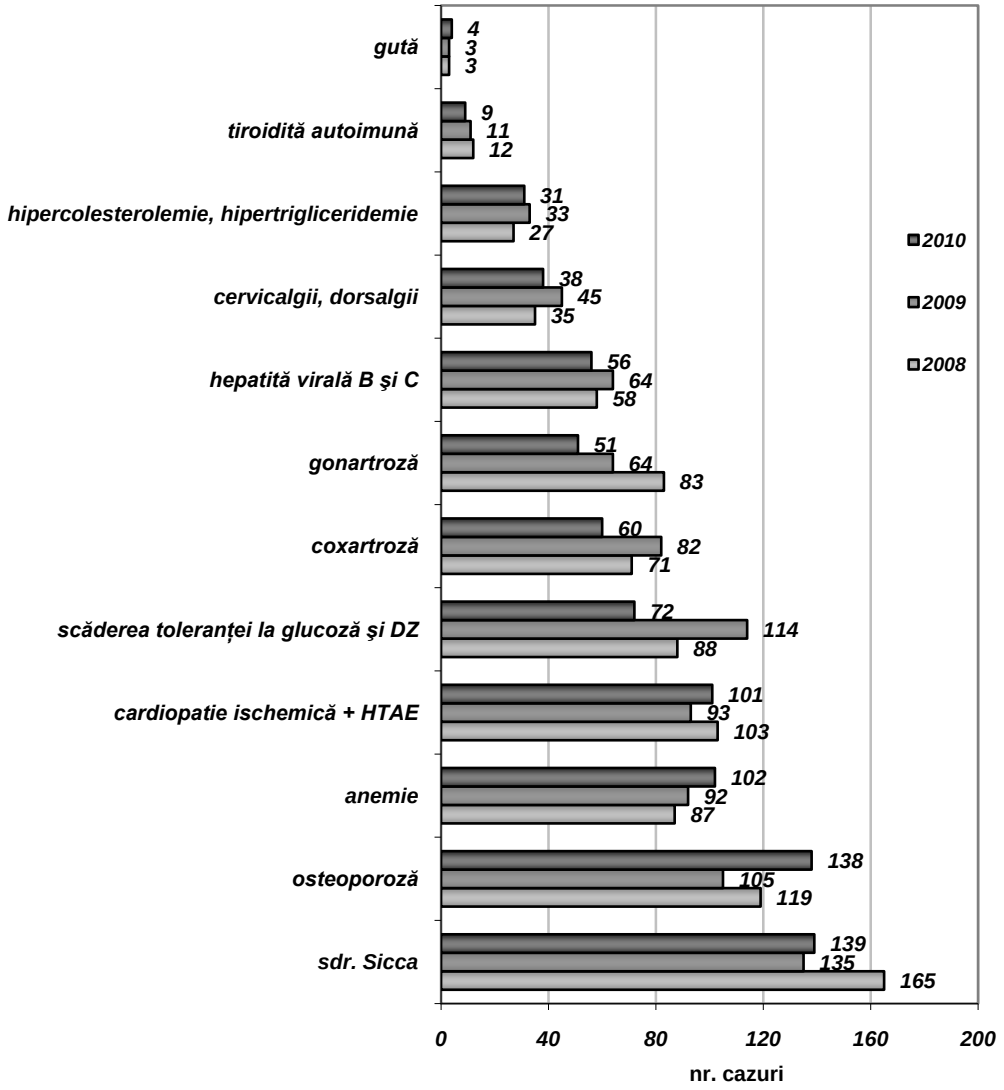

Fig. 3. Distribuţia pe comorbidităţi a cazurilor de poliartrită reumatoidă

3. Unele investigaţii de laborator efectuate la pacienţii luaţi în studiu

Bolnavii cu poliartrită reumatoidă au fost investigaţi în relaţie cu funcţia hepatică (ALT, AST, GGT), renală (acid uric, creatinină, urocultură), glicemia, semnele de anemie, semnele de inflamaţie (ASLO, CRP, VSH), prezenţa diferitelor tipuri de anticorpi (Ac anti HBc, anti Hbe, anti VHC) sau antigene virale (Ag HBs), crioglobulinele şi prezenţa factorului reumatoid (prin metoda Latex şi Waaler-Rose). Luând în discuţie doar prezenţa factorului reumatoid, am constatat că acesta a fost prezent în diferite titruri la 393 pacienţi (55,9%) şi negativ la 310 bolnavi investigaţi (44,1%). Prezenţa

factorului reumatoid a fost documentată la mai multe valori, cele mai frecvent întâlnite fiind titrul de 64, în 48 cazuri (51,6%) şi de 128, la 46 pacienţi (49,5%) (fig. 4).

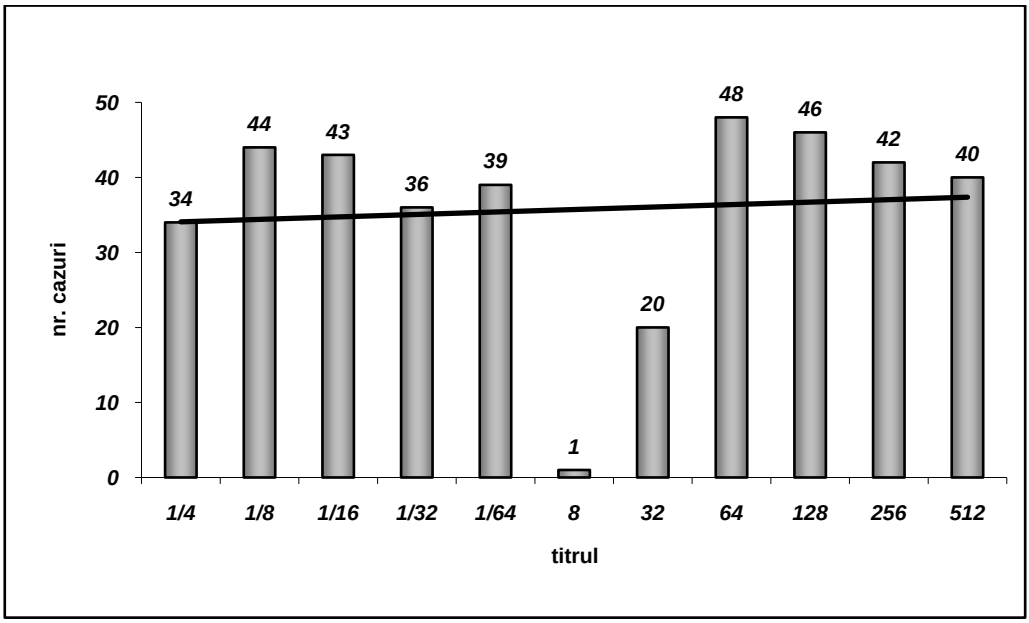

Fig. 4. Factorul reumatoid la pacienţii cu poliartrită reumatoidă (Latex)

CONCLUZII

Dificultăţile în realizarea diagnosticului precoce, care ar favoriza obţinerea unor rezultate terapeutice optime şi consecutiv, reducerea impactului, uneori dezastruos, asupra bolnavului, familiei şi societăţii, situează poliartrita reumatoidă între patologiile cu severe implicaţii sociale şi economice.

Aproape jumătate dintre pacienţii cu poliartrită reumatoidă, incluşi în lotul de studiu (40,2%) a aparţinut grupei de vârstă de 61 ani şi peste, persoane cu o activitate fizică mai redusă, posibil, din cauza pensionării, dar şi a prezenţei comorbidităţilor. Acest fapt poate avea influenţă asupra terapiei, în special asupra kinetoterapiei, exerciţiului fizic şi recuperării pacienţilor.

NOUTĂȚI

PACIENŢII PEDIATRICI CU DISFUNCȚII ALE TRACTULUI URINAR INFERIOR – CALITATEA VIEȚII LOR ŞI A CELOR CE ÎI ÎNGRIJESC

Interesul privind calitatea vieţii (QoL) a crescut iar aceasta este un instrument util pentru evaluarea şi compararea furnizării de ingrijiri medicale şi impactul pe intervenţiile asupra stării de sănătate. Percepţia QoL diferă de la un individ la altul. Caracterizarea QoL este deosebit de dificilă în grupa de vârstă pediatrică, unde fiecare stadiu de dezvoltare prezintă necesităţi diferite. Prevalenţa disfuncţiilor congenitale ale tractului urinar inferior este mare şi îngrijirea acestora modifică rutina zilnică a pacientului şi a familiei sale. Într-un studiu transversal, autorii au evaluat QoL a 28 copii şi adolescenţi cu malformaţii urinare şi a celor ce îi îngrijesc folosind un chestionar (Autoquestionnaire Qualité de Vie Enfant Imagé-AUQUEI) respectiv forma scurtă 36 (Short –Form 36 – SF 36) şi au comparat rezultatele cu un grup –control de 38 copii sănătoşi de vârstă comparbilă/persoane ce îi îngrijesc. Patru întrebări au fost adăugate la chestionarul pacienţilor pentru a evalua problemele legate de îngrijirea lor urologică. Rezultatele au arătat un scor total mic AUQUEI în grupul pacienţilor ($p<0,213$, test Fisher), care au de asemenea probleme în ceea ce rpiveşte aspectele sociale, cum ar fi să se afle în clasă, manifestau trăiri negative în relaţie cu pierderile urinare diurne dar păreau să se adapteze bine la cateterizarea intemitentă. Tendinţa pentru un scor nefavorabil QoL a fost înregistrat şi pentru persoanele de îngrijire din grupul pacienţilor, în legatură cu durerea şi limitarea domeniilor fizice. (Lopey M, Farraro A, Filho UD, Kuczinski E, Koch V, Quality of life of pediatric patients with lower urinary tract dysfunction and their caregivers. *Pediatr Nephrol* 2011; 4(26), 571-577).

CLASSIFICATION AND STAGING SYSTEMS FOR HILAR CHOLANGIO-CARCINOMA (KLATSKIN TUMORS): CLINICAL APPLICATION AND PRACTICAL RELEVANCE (Abstract): Hilar cholangiocarcinomas or Klatskin tumors have been classified in 1975 by French surgeons Henri Bismuth and Marvin B. Corlette and this remains largely used in clinical practice. The authors present the TNM classification and the changes introduced by the sixth and seventh edition of Union for International Cancer Control regarding the tumors of the proximal bile duct and describe Blumgart classification for tumors of this site. The usefulness of these systems is assessed considering the last six years experience of the service**. Key words**: HILAR CHOLANGIOCARCINOMA, KLATSKIN TUMOR, TNM CLASSIFICATION, STAGING

Colangiocarcinoamele sunt tumori dezvoltate din epiteliul ductal biliar. Ele pot apărea în orice segment al ductelor intrahepatice sau extrahepatice, de la ficat pînă la ampula Vater.

Cele care interesează confluența biliară sau colangiocarcinoamele hilare (CCH) au fost descrise de Gerald Klatskin în 1965 (1) primind ulterior acest eponim. De interes este faptul că trei cazuri de o astfel de tumoră fuseseră descrise 8 ani mai devreme de către William A. Altemeier de la University of Cincinnati (2), fapt menționat de către Klatskin în lucrarea sa, ceea ce a îndreptățit pe unii autori să denumească aceste tumori Altemeier- Klatskin (3).

MATERIAL SI METODĂ

În perioada 2005-2010 au fost internați în Clinica a III-a Chirurgicală Iaşi 43 de pacienți cu diagnosticul de tumoră Klatskin. Au fost studiate foile de observație clinică, din care au fost extrase detaliile referitoare la intervențiile chirurgicale efectuate cu intenție curativă şi rezultatele examinărilor anatomo-patologice, urmărindu-se evidențierea concordanțelor clasificărilor şi stadializărilor uzuale.

REZULTATE

Intervenție chirurgicală cu intenție curativă s-a efectuat la 3 pacienți, restul intervențiilor fiind paliative sau laparotomii exploratorii.

Primul pacient, de 72 de ani, cu tumoră la nivelul convergenței canalelor hepatice, a beneficiat de rezecția căii biliare extrahepatice cu anastomoză bi-hepatico jejunală

pe ansă „în Y”. Examenul anatomo-patologic extemporaneu a confirmat tranşele de secţiune negative ale căilor biliare în segmentele proximal şi distal, iar cel definitiv a evidenţiat doi limfoganglioni regionali cu metastaze de colangiocarcinom.

La al doilea pacient, de 49 de ani, cu tumoră interesând convergenţa canalelor hepatice, cu extensie la nivelul canalului hepatic stâng s-a realizat hepatectomie stângă (segmentele II, III şi IV) şi rezecţia segmentului I, în bloc cu calea biliară principală (secţionată distal în segmentul retroduodenal), calea biliară restantă de la nivelul hemificatului drept situându-se pe canalele sectoriale anterior şi posterior; continuitatea biliodigestivă s-a realizat, după completarea limfadenectomiei regionale, pe o ansă jejunală „în Y” à la Roux suturata la teaca pediculilor glissonieni ai sectoarelor drepte. Examenul anatomo-patologic a evidenţiat absenţa metastazelor ganglionare.

Celui de-al treilea pacient, în vârstă de 63 de ani, cu tumoră Klatskin având extindere tot pe canalul hepatic stâng, i s-a efectuat rezecţia căii biliare principale în bloc cu hemificatul stâng (segmentele II, III şi IV), anastomoză colangio-jejunală la nivelul tranşei de rezecţie a canalului hepatic drept; ganglionii regionali nu au fost găsiţi invadaţi.

DISCUŢII

Cronologic, *prima clasificare* a CCH a fost cea propusă în 1975 de către Henri Bismuth şi Marvin B. Corlette (4), larg folosită şi astăzi, în variantă modificată, fiindcă articolul original cuprindea numai primele trei tipuri (tab. I).

Ea grupează tumorile pe baza extensiei lor longitudinale în sistemul ductal hepatic, fiind o clasificare anatomică (fig.1), care poate ghida terapia (rezecţională sau paliativă) însă nu poate preciza care dintre pacienţi sunt candidaţi chirurgicali şi nici nu furnizează informaţii privind prognosticul sau corelaţii cu rata de rezecabilitate (5).

TABELUL I

Clasificarea Bismuth-Corlette

Tipul I: tumora invadează confluenţa biliară dar canalele drept şi stâng comunică
Tipul II: tumora invadează confluenţa biliară iar canalele drept şi stâng nu comunică
Tipul III: tumora invadează confluenţa biliară şi are extensie pe canalele hepatice IIIa: extensie pe canalul hepatic drept IIIb: extensie pe canalul hepatic stâng
Tipul IV: tumora este multicentrică sau invadează canalele hepatice drept şi stâng

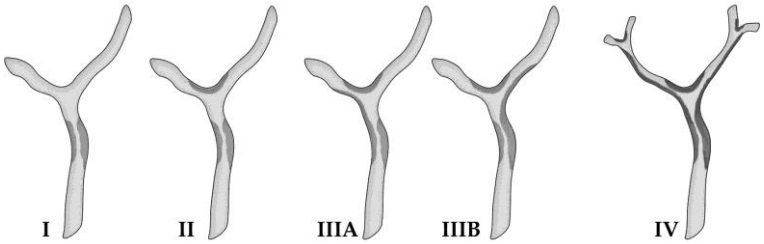

Fig. 1. Reprezentarea schematică a clasificării Bismuth- Corlette

Cel mai răspândit şi folosit sistem de clasificare a tumorilor solide este bazat pe aprecierea extinderii tumorale (T), a interesării ganglionilor (nodulilor) limfatici regionali (N) şi a prezenţei metastazelor la distanţă (M), cunoscut sub denumirea abre-

viată TNM, care permite planificarea tratamentului şi estimarea prognosticului. Compararea diagnosticelor şi terapiilor este posibilă dacă extensia neoplazică anatomică este definită conform standardelor general acceptate (6).

În ianuarie 2003 Union for International Cancer Control (UICC) a introdus în uz a şasea ediție a clasificării TNM a tumorilor maligne (7). Aceasta a introdus *modificări majore* în clasificarea cancerelor căii biliare extrahepatice, renunțându-se la diferențierea între invazia *presupuselor* diferitelor straturi parietale ale căii biliare principale precum „țesutul conjunctiv subepitelial (T1a)", „stratul fibromuscular (T1b)" sau „țesutul conjunctiv perifibromuscular (T2)" din ediția a cincea (8).

Astfel, tumora T1 este limitată la calea biliară, iar dacă invadează dincolo de calea biliară este clasificată T2. În cazul unei boli mai extinse, cu invazia ficatului, vezi-culei biliare, pancreasului şi/ sau tributarelor unilaterale ale venei porte sau arterei hepatice, tumora este stadializată T3 şi T4 atunci când invadează oricare din următoarele: vena portă sau tributarele bilateral, artera hepatică comună sau alte structuri adiacente

O altă modificare majoră a constat în contopirea categoriilor N1 şi N2 în N1, metastaze în ganglionii regionali.

Noutățile ultimei ediții (9) intrată în uz în ianuarie 2010 sunt reprezentate de clasificarea cancerelor căii biliare extrahepatice în proximale (cuprinzând canalele hepatice drept, stâng şi cel comun) şi distale (de la abuşarea cisticului în canalul hepatic comun), cu diferențe în definirea categoriilor TNM şi a stadializării; de asemenea, dispariția categoriei Mx din toate stadializările tumorilor solide.

Definițiile categoriilor T, N şi M pentru CCH ale ediției a şaptea se regăsesc în tabelul II iar stadializarea în tabelul III.

TABELUL II

Parametrii TNM ai clasificării UICC, ediția a 7-a, pentru cancerele căilor biliare extrahepatice proximale

T- tumora primară	
T1	Tumoră limitată la calea biliară
T2a	Tumora invadează dincolo de peretele căii biliare
T2b	Tumora invadează parenchimul hepatic adiacent
T3	Tumora invadează tributare unilaterale ale venei porte hepatice sau arterei hepatice
T4	Tumora invadează trunchiul venei porte sau tributarele bilateral şi/sau artera hepatică comună
N - ganglioni limfatici regionali (GL)	
N0	Fără metastaze în GL regionali
N1	Metastaze în GL regionali
M- metastaze la distanță	
Mx	*CATEGORIE ELIMINATĂ DIN TOATE STADIALIZĂRILE TNM!!!*
M0	Fără metastaze la distanță
M1	Metastaze la distanță

TABELUL III

Stadializarea cancerelor căilor biliare extrahepatice proximale

Stadiul I	T1	N0	M0
Stadiul II	T2a-b	N0	M0
Stadiul IIIA	T3	N0	M0
Stadiul IIIB	T1-3	N1	M0
Stadiul IVA	T4	Orice N	M0
Stadiul IVB	Orice T	Orice N	M1

Al treilea sistem de clasificare a CCH a fost propus de grupul condus de Leslie H. Blumgart de la Memorial Sloan-Kettering Cancer Center (MSKCC) din New York, acesta fiind o modificare a parametrului T al sistemului American Joint Comission on Cancer (AJCC), care ia în considerare trei factori legaţi de extensia tumorală, identificaţi de imagistica preoperatorie (10,11,12). Aceşti factori sunt: situarea şi extinderea invaziei biliare (conform clasificării Bismuth-Corlette), prezenţa sau absenţa invaziei portale şi prezenţa sau absenţa atrofiei hepatice lobare. Studiul publicat în 1998 cuprindea patru categorii T, cel din 2001 numai trei, prin comasarea a două categorii din propunerea iniţială (11,12) (tab. IV).

Scopul acestor modificări este categorizarea acelor pacienţi care sunt candidaţi pentru explorare chirurgicală cu intenţie rezecţională curativă ca şi furnizarea de informaţii anatomice privind extensia tumorală locală . Această clasificare nu a fost însă adoptată şi de alţi autori.

Este de amintit că în 1985 Gazzaniga (13) a publicat propria procedură de stadializare, care ţine seama şi de extinderea extrabiliară a tumorilor, în primul rând posibila interesare vasculară, arterială sau portală, care s-au regăsit ulterior în clasificările UICC. Mai mult, în această clasificare, îmbunătăţită ulterior (14) fiecare stadiu tumoral este corelat cu potenţialul terapeutic – tratament chirurgical curativ în stadiile 1- 3 sau paliativ în stadiul 4. Această clasificare nu a avut, însă, impactul şi notorietatea celorlalte trei menţionate.

TABELUL IV

Definirea parametrului T în clasificarea Blumgart

Stadiu	Criterii
T1	Tumora invadează confluenţa biliară+/- extensie unilaterală la ramuri biliare de al doilea ordin
T2	Tumora invadează confluenţa biliară+/- extensie unilaterală la ramuri biliare de al doilea ordin **şi** invazie venoasă portală ipsilaterală +/- atrofie hepatică lobară *ipsilaterală*
T3	Tumora invadează confluenţa biliară + extensie bilaterală la ramurile biliare de al doilea ordin ; **sau** extensie unilaterală la ramuri biliare de al doilea ordin cu invazie venoasă portală contralaterală; **sau** extensie unilaterală la ramuri biliare de al doilea ordin atrofie hepatică lobară contralaterală; **sau** invazie venoasă portală bilaterală sau a trunchiului principal

Majoritatea covârşitoare a pacienţilor cu stricturi hilare şi icter au tumoră malignă (15). Diferenţierea benign - malign a stricturilor hilare este dificilă şi reprezintă o problemă majoră în managementul acestor leziuni, 10-15% din pacienţi fiind de aşteptat să aibă alt diagnostic decât CC (16).

Diagnosticul diferenţial al leziunilor stenotice de la nivelul hilului hepatic include-colangiocarcinomul, metastazele ganglionare limfatice, colangiocarcinomul intrahepatic cu extensie hilară, limfomul Hodgkin şi non-Hodgkin, respectiv coledoco-litiaza, sindromul Mirizzi, granuloamele, fibroza benignă, tuberculoza, sechelele traumatice sau postoperatorii, fibroza retroperitoneală (15,17,18).

Pacienţii din studiul nostru au fost încadraţi postoperator (Bismuth-Corlette şi TNM) după cum urmează: primul pacient - tip II Bismuth-Corlette şi stadiul IIIB (T1N1M0); al doilea pacient - tip IIIb Bismuth-Corlette şi stadiul IIIa (T3N0); al treilea pacient- tip IIIb Bismuth-Corlette şi stadiul II (T2N0).

Comparativ, clasificarea Bismuth-Corlette preoperatorie, făcută pe baza explorărilor imagistice (colangio-RMN şi computer-tomografie) a clasificat pacienţii în mod diferit. Astfel, la primul pacient tumora a fost supraevaluată imagistic (tip IIIb) datorită dificultăţilor de a obţine detalii la o rezoluţie mai mare de achiziţie şi prelucrare a imaginilor . La doilea pacient, de asemenea suprastadializat (tip IV), tumora de confluent biliar superior a fost etichetată ca având şi invazie arterială şi de perete venos portal, condiţie infirmată la disecţia perivasculară care a făcut posibilă izolarea tumorii de elementele vasculare la nivelul plăcii hilare. La cel de-al treilea caz examinarea tomografică a descris o tumoră de dimensiuni mai mici faţă de cele reale (tip II, substadializare), extensia tumorii nefiind precizată corect datorită caracterului infiltrativ.

Se remarcă neconcordanţele dintre încadrarea cazurilor în tipuri Bismuth-Corlette pre- şi postoperator, ceea ce confirmă limitele acestei clasificări. Simplitatea şi claritatea o fac însă larg şi cvasi-general folosită pentru caracterizarea CCH.

Pe de altă parte, stadializarea TNM fiind stabilită postoperator nu poate fi utilizată în conturarea strategiei terapeutice şi prognosticului în faza iniţială. În schimb, fiind standardizată şi efectuată în toate cazurile constituie baza comună de comparare a oricărei serii raportate în literatură.

În practica serviciului nostru nu a fost utilizată stadializarea propusă de Blumgart şi colectivul de la MSKCC New-York.

Studiul, chiar realizat pe un număr extrem de mic de pacienţi (atât datorită rarităţii acestui tip de tumoră cât şi numărului şi mai mic de pacienţi rezecabili) a permis ajungerea la concluzii similare celor din literatură.

CONCLUZII

Clasificarea Bismuth-Corlette a colangiocarcinoamelor hilare (tumorile Klatskin) este limitată doar la descrierea extensiei longitudinale a tumorii şi este larg folosită în practica clinică. Clasificarea TNM reprezintă standardul internaţional şi cunoaşte modificări continue de la o ediţie la alta, dar nu s-a dovedit a avea valoare prognostică preoperatorie, iar clasificarea Blumgart are calităţi privind prognosticul dar nu este utilizată decât de centrul în care a fost propusă.

ANAL AND PERIANAL DISORDERS MANAGEMENT(Abstract): Perianal disorders are the main cause of addressability to the family doctor and to the gastroenterologist. The study is conducted on the background of the increasing incidence of anal pathology in relation with the decrease in the age of appearance. **Aim**: to propose a protocol for management of patients with perianal disease. **Material and methods:** The study included a group of 2,000 patients, who were clinically and imagistic investigated. **Results**: The statistics show a much higher incidence of perianal pathology and an increasing prevalence of it in younger age. **Conclusions**: we propose a management plan for these patients that facilitates early diagnosis and determines the specific treatment required. The impact of this study is both medical and socio-economic as it shortens patient suffering and the time required for active social reintegration. **Keywords**: PERIANAL DISORDERS, HEMORRHOIDS, MANAGEMENT, ANAL DISEASES.

Perianal disorders are the main cause of addressability to the family doctor and to the gastroenterologist. The wide range of pathologies, from benign (hemorrhoids, anal fissures, fecal incontinence, fistulas and perianal abscesses, thrombosis) to malignant (rectal carcinoma), involves a clinical examination and a complete and correct anamnesis (1)

Anal fissure is a linear or oval ulcer in the anal canal below the dentate line extending to the anus. The most frequent location is at the posterior median line, being explained by several theories with anatomical substrate: the elliptical shape of the external anal sphincter, which leads to low resistance of anal canal and relative ischemia of the posterior commissure, which compromises the blood circulation and increases anal sphincter tonus (2).

Hemorrhoids are the increasing and/or distal movement of protrusions of the anal mucosa formed by smooth muscle and blood vessels, along with connective tissue, termed "cushions". Hemorrhoids usually consists of three cushions in the left lateral, right anterior and right posterior positions (2).

These anatomical structures are in the submucosal layer of fibrovascular tissue and due to lack of smooth muscle wall are considered as sinusoidal structures. Hemorrhoids are suspended in the anal canal due to Treitz's muscle, thus explaining the increase in the incidence of pathology with aging, because of the loss of the muscular tonus. When they increase their size become pathological, because of the venous stasis. This process can be accelerated by other pathologies such as high blood pres-

sure, portal hypertension, and abdominal tumors.

Anal cryptitis and papillitis are inflammatory proctologic illnesses with increased incidence. Papillitis is the inflammation of the anal papillae at the distal end of Morgagni's rectal columns. Cryptitis is the inflammation of an anal crypt and corresponding anal glands immediately above the dentate line. Initially, the inflammation occurs at the crypt of Morgagni, and then extends to the anal papilla. Inflammation of the papilla due to the cryptitis and its volumetric growth increase the likelihood that fecal material remains captive in the crypt and initiates inflammation, and if it forms the abscess, anal fissure and perianal fistula may occur.

Cryptoglandular fistula is the most common cause of perianal infection and affects especially males. It represents the infection of the Hernmann and Desfosses glands from the intersphincteric space and their opening to the crypts of Morgagni (1, 2).

Malignant pathology of the perianal region includes rectal cancer as a subtype of colorectal cancer (CCR) and anal cancer. In colorectal cancer, neovascularization is a critical event during tumor genesis, with an early peak in malignant process (3-8). Rectal cancer has a worse prognosis because it is characterized by an increased rate of local recurrence and a higher metastasis presence at the moment of diagnosis (9).

MATERIAL AND METHODS

This retrospective study was performed in a group of 2,000 patients, investigated at Medical ON Group, Iasi, between 12.04.2015-14.05.2018, with ages between 20-80 years old, of which 63% were men and 37% women.

Patients presented with various perianal pathologies: hemorrhoids, perianal abscesses fistula, condylomatosis, various anal and rectal tumors and anal polyps. Patients' anamnesis was performed, following the clinical manifestations, methods of investigation and the therapeutic methods used in the past, followed by the clinical examination of the perianal region and the anal canal. This was done by rectal digital examination, video-anuscopy, and in some cases by rectoscopy to confirm or refute the presence of a colorectal tumor (up to 25 cm) or ulcerative colitis.

A total of 2,050 minimally invasive interventions were performed, such as: rubber band ligation, infrared coagulation and resection with radiofrequency cautery. Using statistical methods, we calculated the prevalence of perianal affections according to the associated risk factors.

RESULTS

We calculated the proportion of each disease in total perianal pathology by reporting the total number of patients with certain pathology in total patients with perianal pathology (tab. I).

TABLE I

The distinctive variation of pathologies in total perianal pathologies

	Hemorrhoid	Perianal abscesses	Perianal fistula	Anal polyps	Anal papilloma	Condylomatosis	Squamous-cellular cancer	Rectal cancer
2015	89.90%	2.57%	1.28%	3.85%	0.51%	0.25%	0.25%	1.28%
2016	84.50%	6.34%	2.11%	4.22%	0.21%	0.63%	0.42%	1.47%
2017	87.64%	7.17%	1.18%	1.66%	0.16%	0.66%	0.50%	1.00%
2018	89.42%	3.15%	4.26%	1.66%	0.37%	0.37%	0.18%	0.55%

The environment from which the patient originates is also important. The emergence of an increasing number of sedentary persons in cities, correlated with the reduced addressability to doctors of the patients in the rural areas leads to significant statistical differences between the two situations (fig. 1).

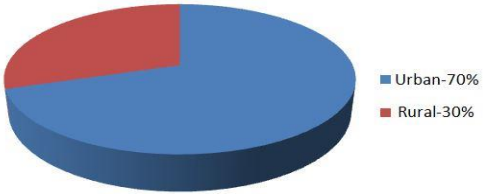

Fig. 1. Distribution of patients according to their origin

The distribution of patients by age and gender shows an increased prevalence of male perianal pathology and draws an alarm signal related to the early onset of age. The most affected age group oscillates between 30-60 years old, with an apex of 40-50 years (72%), as demonstrated in the literature, with respect to the group of 20-30 years, where the incidence of pathologies is low (2 %). We observed that at the age at which the incidence of perianal pathology is increased (40-50 years old) men are 1.6 times more affected than women in the study group (fig. 2).

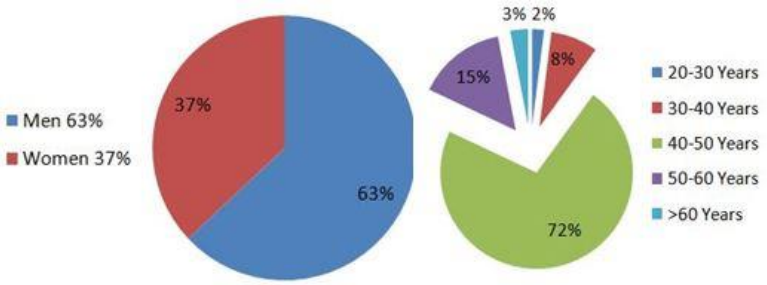

Fig. 2. Distribution of patients by age and gender

We have structured the types of studied pathologies as a percentage of the perianal disease and we observed that prevalence of hemorrhoidal disease is 88% with a total of 1,757 cases since 2,000 and the low prevalence of benign (70 cases) and malignant (28 cases) tumors between 12.04.2015-14.05.2018. In the case of patients with hemorrhoids, the anuscopy revealed a small number of anatomical atypia, 10% presenting turgescent vascular bundle outside the three major bundles. As symptoms, lower digestive hemorrhage and proctalgia are the most frequent.

From the analysis of the living and working conditions of the study group, we obtained data about the occupation and the time spent in the seating position (fig. 3). It was obvious that in the study group, patients with more than 5 hours per day in seating position had an increased risk for perianal diseases.

There is an increased prevalence of hemorrhoidal disease compared to other pathologies, most of the cases being diagnosed in 2015-2016, most of them being men, from urban areas, aged 40-50 years, the most common, in over 50% being hemorrhoidal disease, perianal abscess, perianal fistula and anorectal polyp and the physical activity rate being slightly low, 55% of them spending 5-10 hours in the sitting position.

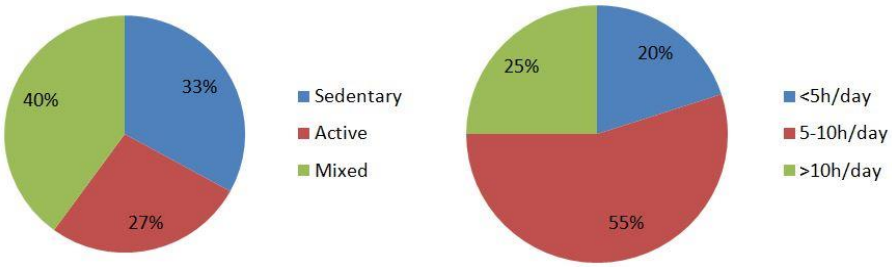

Fig. 3. Distribution of patients according to type of job and time spent sitting

DISCUSSION

Specific prevalence on pathologies over the period 2015-2018 according to the formula Prevalence of period = total number of cases of illness / number of examined persons X 100, were 50% for hemorrhoidal pathology, 4% for perianal abscess, 1.8% for perianal fistula, 2.16% for perianal fissure, 2.16% for anorectal polyps, 0.24% for anal papilloma, 0.4% for condylomatosis, 0.28% for squamous cell cancer and 0.84% for rectal cancer.

Particular attention should be paid to patients with chronic cardiovascular pathology, pacemaker carriers. At the same time, we noticed a special category of patients - vocal artists and those using wind instruments. In their case, the intraabdominal pressure raised during artistic act by contraction of the abdominal anterolateral muscles, correlated with a high vocal tract, can cause the hemorrhoidal disease in time (10-12).

Following anamnesis, the dominant symptom was bleeding with red blood, small but repetitive abundance, conditions that led patients to see their doctor. Of these, 100 patients experienced pain, especially patients who had complicated hemorrhoids with thrombosis. The patient's reported swelling was 70% due to the hemorrhoid prolapse of Stage III-IV. Serum mucosal leakage was also reported in 35% triggering anal pruritus. The beginning of symptoms was acute, first-degree hemorrhoids patients presenting to their physician immediately, and those with a chronic evolution either did not take self-medication or used various unguents (13-17).

The minimally invasive surgical interventions in the ambulatory (18-23) were grouped as follows: 71 patients under IRC (infrared coagulation), 1,686 for RBL (rubber band ligation), 100 incisions and drainage, 17 fistulectomies, 28 fistulotomies, 19 excisions, 2 curettage and 5 excisions and curettages.

Following the study, we have proposed a protocol for ambulatory patient management:

- **Patient's history:** to insist on the symptoms, disease evolution, the debut, the medical history, the exposure to risk factors: sedentary, sitting position - for the benign pathologies and abuse of alcohol, smoking, HIV virus, sexually unprotected anal sex - for malignant pathology or condylomatosis.
- **Clinical examination**: inspection of the anal and perianal region may reveal external fistulae that secretes pus, the presence of lesions produced by laceration in the case of acute anal fissure, or the presence of the tegument impression at the distal end of the chronic fissure. In case of prolapsed internal hemorrhoids, the anal

mucosa appears together with the turgescent venous formation at the level of the anal ring and in the case of the superficial perianal abscess it can be observed an area showing signs of inflammation. Papilloma and prolapsed anal polyps are a perianal skin color formation at the anal orifice. Condylomatosis is white formation, in the anal or perianal orifice or perianal skin. In the case of malignant pathology, these formations may be elastic, mobile in the case of polyps or may be friable, stenotic, and harsh.

- **Imagistic evaluation**: video scanning, eventually fistulography and exploration of the fistula with a buttoned probe and in the case of suspicion of rectal cancer, anal cancer or acute and chronic complicated perianal suppuration, it is recommended to perform a CT, MRI or PET-CT.
- **Preoperative evaluation** with the anamnesis orientated to possible allergic reactions, the medication taken by the patient, the anesthetic-surgical history, possible postinterventional complications, stopping or passing the antiaggregant / anticoagulant therapy on fractional low molecular weight heparin.
- **Treatment** of hemorrhoidal disease is performed according to their degree and complications: in grade I - prophylactic treatment, local and general administrated drugs, minimally invasive - infrared coagulation; in grade II-III - prophylactic, local and general medical treatment, minimally invasive - infrared coagulation corroborated with Rubber Band Ligation; in grade IV - prophylactic, local and general medical treatment, minimally invasive - infrared coagulation, in conjunction with Rubber Band Ligation and classic surgical treatment in case of relapses. In: perianal abscess - incision, evacuation and drainage; perianal fistula - fistulotomy, fistulectomy; anorectal polyps, anal papillae - radiofrequency excision; acuminate condylomas - excision and curettage with radiofrequency (24, 25).

CONCLUSIONS

Under modern society, most patients do not have the time to hospitalize, this problem being solved by minimally invasive ambulatory treatment due to by lack of hospitalization, anesthesia, complications, minimal risks with efficiency, speed and safety, and reducing recovery days. In the last years there has been an increase in the incidence of hemorrhoidal disease (especially) among the young population (20-30 years), with direct socio-economic implications. This is due to the emphasis on sedentary life, especially in the urban areas, but also on labor migration to new areas such as IT.

FACTORS AFFECTING EARLY MORBIDITY AND MORTALITY IN NON-SMALL CELL LUNG CANCER SURGERY, THE EXPERIENCE OF SURGICAL CLINIC NO. 1, TG. MUREŞ (Abstract): **Introduction.** The incidence of lung cancer has increased alarmingly. Lung cancer represents the first cause of death in men. Thoracic surgery is engraved with increased morbidity and mortality. Therefore, a rigorous selection of patients undergoing such surgery is imposed. In order to establish the correct therapeutic attitude,paraclinical explorations are of the ulmost importance. **Material and methods:** We conducted a retrospective observational study over a period of six years. We used the casuistry of Surgical Clinic no. 1, Mureş County Emergency Hospital. We studied the observation sheets of all the patients admitted in the Surgical Clinic no. 1 over a period of six years (1th of January 2005 to the 31th of December 2010). We studied 197 patients admitted to surgery in our clinic for lung cancer. **Results**: In the group studied, the majority of patients were in the 5th and 6th decade of life. The average age was 59.48 years. In our study group, most patients were in an advanced stage of the disease, probably due to the late stage diagnosis of lung cancer in general. The majority of the patients were in the stage IIB and IIIA of disease. The overall postoperative morbidity rate was 21.82% (43 cases), In the study group we registered 8 deaths (4.06%) – it should be noted that we considered in-hospital mortality within the first 30 days postoperatively. **Conclusions:** The main risk factors for postoperative complications are: late age, male gender, pneumonectomy, low FEV_1 value. Certain risk factors are predictive of postoperative mortality. The most important of them are: late age, male gender, type of surgery, FEV value, associated diseases (especially cardiovascular and diabetes). **Key words**: LUNG, CANCER, MORBIDITY, MORTALITY, FISTULA

In the past decades the incidence of lung cancer has increased alarmingly. It represents the principal cause of death in both men and women in the United States of America (1).

In our country, the incidence of lung cancer has increased dramatically in the last 10 years, becoming the most frequent type of cancer in men and the third one in women (after breast cancer and cervical cancer). In 1990, the incidence ratio men/women was 9 to 1, now it has reached 2 to 1.

The purpose of the present study is to evaluate the most important factors that af-

fects early morbidity and mortality of patients with lung cancerthat were admitted and operated in the Surgical Clinic nr. 1 of the Mureş County Emergency Hospital, for over a period of six years, between the 1th of January 2005 and the 31th of December 2010.

MATERIALS AND METHODS

We conducted a retrospective observational study over a period of six years. We used the casuistry of Surgical Clinic nr. 1, Mureş County Emergency Hospital. We studied the observation sheets of all the patients admitted in the Surgical Clinic nr.1 over a period of six years (1th of January 2005 to the 31th of December 2010). We studied 197 patients admitted to surgery in our clinic for lung cancer.

The 197 patients in the study were divided into two groups :

- Group A : patients with malignant lung tumors that underwent typical pulmonaryresections (lobectomy, bilobectomy or pneumonectomy).
- Group B : patients with malignant lung tumors that underwent atypical pulmonary resections (wedge resections, exploratory thoracotomy with biopsy).

A standard set of preoperative investigations were performed on all the patients, necessary for both diagnostic purposes and for the type of surgery. Thus, the following tests were carried out : blood tests (blood count, biochemistry and coagulation), chest radiography in two incidents, chest CT, ventilatory function tests, ECG, echocardiography.

Staging was preformed postoperatively, using the TNM system (pTNM).

RESULTS

We have entered into the study 197 patients admitted with malignant lung tumors in the Surgical Clinic Nr. 1 in the period 1th of January 2005 to the 31th of December 2010. The two groups used were :

- Group A : 106 patients (53.8%) that underwent typical resections (lobectomy, bilobectomy, pneumonectomy)
- Group B : 91 patients (46.2%) that underwent wedged resections and exploratory thoracotomy

In terms of distribution per year of patients taken into the study, we obtained a relatively uniform distribution of cases. By studying the observation sheets of patient's and Surgical Clinic nr.1's casuistry, we obtained the following distribution of cases by year :

Of the 197 patients studied, 41 were women (20.82% of the cases) and 156 were men (79.18% of the cases).

Most patients were in the 5th and the 6th decade of life. The average age of patients in the study was 59.48 years. The average age in the group of men was 57.07 years, and in the group of women was 60.12 years. The P value was calculated to be 0.107 so there is no statistically significant diffrence between the age of patients.

In the group studied the vast majority of patients were smokers – 160 patients (81.21%) – the role of smoking as a risk factor in the etiology of lung cancer is well known. In terms of the correlation between smoking and the sex of the patients, 35 women (85.36%) and 125 men (80.12%) were smokers. From a statistical viewpoint, the p value was calculated to be 0.502 so we can not say that there is a statistical association between the two values.

Given the fact that lung cancer generally affects advanced ages, in the groups studied 75 patients (38.07%) had comorbidities. They were represented by : cardiovascular disease : hypertension (28 cases – 14.21%), ischemic heart disease (32 cases – 16.24%), arrhythmia (6 cases – 3.04%), chronic PAD (3 cases – 1.52%), MI scars (6 – cases 3.04%), stroke sequelae(4 cases – 2.03%). We also had patients with respiratory disease : COPD (8 cases – 4.06%), chronic bronchitis (4 cases

TABLE I
Patients / year

Year	Nr. of cases
2005	38 patients
2006	31 patients
2007	30 patients
2008	36 patients
2009	26 patients
2010	36 patients

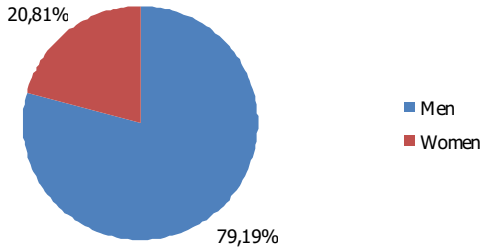

Fig. 1. Distribution of patients according to sex

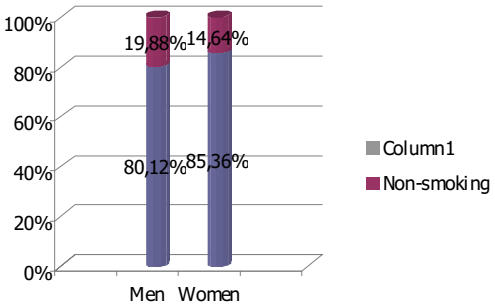

Fig. 2. The incidence of smoking by gender

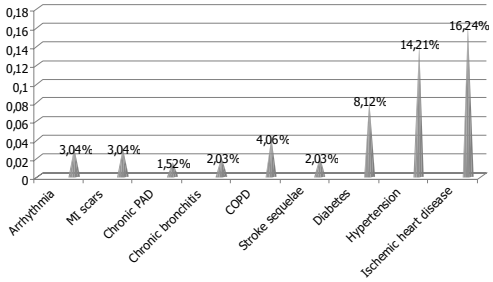

Fig. 3. Associated disorders

– 2.03%). The incidence of diabetes mellitus was 8.12% (16 cases). We also recorded diseases with a lower rate of incidence: GI tract disorders (4 cases – 2.03%), kidney disorders (4 cases – 2.03%), orthopedic disorders (1 case – 0.5%).

By analyzing the FEV parameter (FEV_1), we observed that most patients (53.29% - 105 patients) had a FEV over 60% of the ideal value and 46.71% (92 patients) had a FEV_1 value below 60% of the ideal value. The FEV_1 ideal value is calculated based on age, sex and weight. We used as the standard the value of 60% since the literature considers that patients with a FEV_1 below 60% have a higher risk of pulmonary excision surgery. In terms of distribution according to the two groups studied we observed that:

- in group A (typical resections): 89 patients (83.96%) had a FEV_1 over 60%, and 17 patients (16.04%) had a FEV_1 below 60%
- in group B (wedged resections): 75 patients (82.41%) had a FEV_1 below 60%, and 16 patients (17.59%) had a FEV_1 over 60%

We studied the two groups of patients depending on the type of surgery. In group A we had 106 patients that underwent typical resections: 13 bilobectomy (12.27%), 52 lobectomies (49.06%), 41 pneumonectomies (38.67%). In group B we had 91 patients that underwent atypical resections: 54 wedged resections (59.34%) and 37 exploratory thoracotomies with biopsy (40.66%).

In our study group, most patients were in an advanced stage of the disease, probably due to the late stage diagnosis of lung cancer in general. The distribution of these patients based on disease stage is represented on figure nr. 7. In the analysis of the casuistry based on disease stage we excluded the 15 patients with lung metastases.

In order to study the incidence of bronchial stump fistula we divided the patients that presented this complication into two lots: those who developed the fistula early and those who developed it late. We divided

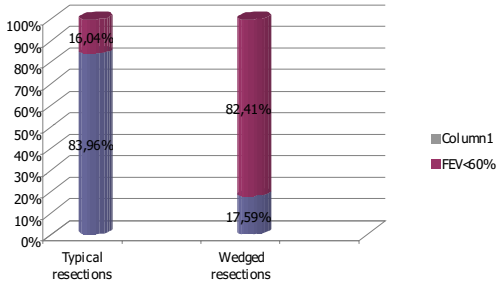

Fig. 4. Groups distribution according to FEV

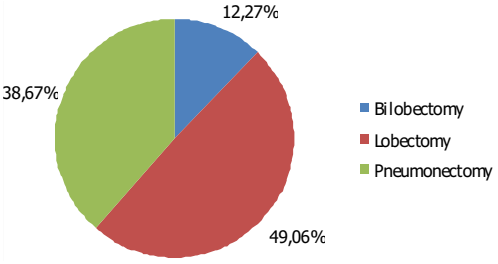

Fig. 5. Distribution of cases that underwent typical resection

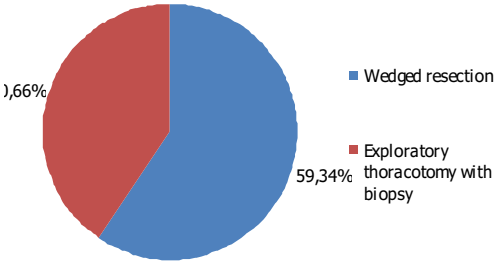

Fig. 6. Distribution of cases that underwent atypical resection

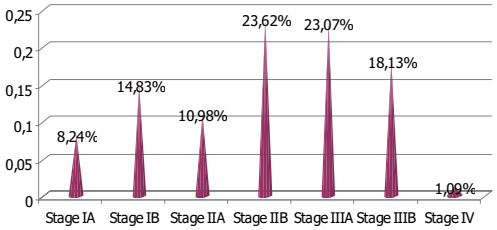

Fig. 7. Distribution of cases according to disease stage

these patients based on the etiological causes that lead to early bronchial stump fistula hence they are different from the ones that are responsible for the apparition of late bronchial stump fistula. The incidence of early bronchial stump fistula was 1.88% (2 cases, 1 right pneumonectomy and 1 left pneumonectomy) while the incidence of late bronchial stump fistula was 4.71% (5 cases : 1 lobectomy, 1 bilobectomy, 1 left pneumonectomy and 2 right pneumonectomies). In all the patients that presented this complication we preferred a conservative approach : passive pleural drainage, pleural cavity lavage with antiseptic solutions on the drain (Betadine), antibiotic treatment according to the sensibility tests from the secretions on the drain and symptomatic treatment.

To analyze the postoperative complications that occurred in our study group we split the complications into 2 lots : minor postoperative complications (non – life – threatening) and major postoperative complications (life threatening). We also took into account the sex of the patients that developed postoperative complications, the type of surgery performed on these patients. We excluded patients with bronchial stump fistulas as we studied them separately. The overall postoperative morbidity rate was 21.82% (43 cases), there were 13 patients (6.59%) who had postoperative complications, both minor and major. The results were as follows :

- Minor postoperative complications : 37 cases (18.78)
- Major postoperative complications : 19 cases (9.64%)

We divided the group of patients who experienced postoperative complications by gender. We observed that 88.37% of them were men (38 cases), compared with 11.63% (5 cases) – women. Thus there is a direct corelation between patients gender and the occurence of postoperative complications, male gender representing an independent risk factor.

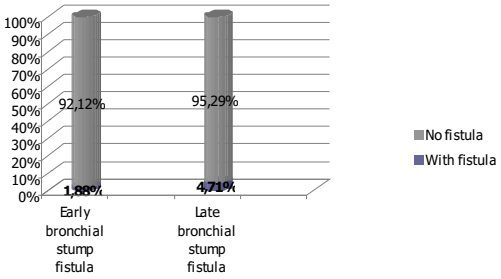

Fig. 8. The incidence of bronchial stump fistulas

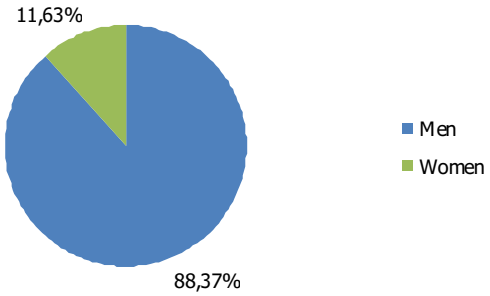

Fig. 9. The correlation between patient's sex and the occurrence of postoperative complications

TABLE II
The incidence of minor postoperative complications

Complications	Nr. of cases	Percentage
Atelectasis	3	1.52%
Bronchial obstruction	3	1.52%
Recurrent laryngeal nerve paresis	2	1.02%
Minor air loses	8	4.06%
Suppuration of the wound	2	1.02%
Arrhythmias	19	9.64%
Total:	37	18.78%

We also took into account the type of surgery performed in patients who had postoperative complications. The distribution was as follows: 3 cases –thoracotomy (6.97%), 16 cases –lobectomies (37.20%), 2 cases – bilobectomy (4.65%), 15 cases – pneumonectomy (34.88%) and 7 cases with wedge resections (16.27%). A total of 33 patients (76.74%) underwent typical pulmonary resections while atypical resections were performed on only 10 patients (23.26%). We thus obtained a direct correlation between the type of surgery and postoperative complications.

We studied the postoperative morbidity rate for each type of surgery and we concluded: 8.10% of patients that underwent exploratory thoracotomy, 12.96% of patients that underwent wedge resections, 30.76% of patients that underwent lobectomies, 15.38% of patients that underwent bilobectomies had postoperative complications. The highest morbidity rate we found was on patients that underwent pneumonectomies (36.58%).

In the study group we registered 8 deaths (4.06%) – it should be noted that we considered in-hospital mortality within the first 30 days postoperatively. The main causes of death were respiratory and cardiovascular failure but we also had one case of acute renal failure.

The main causes of death are shown in the table below:

An independent predictive factor in postoperative mortality and morbidity is the preoperative value of FEV_1. We studied

TABLE III
The incidence of major postoperative complications

Complications	Nr. Of cases	Percentage
Stroke	2	1.02%
Pulmonary embolism	3	1.52%
Acute pulmonary edema	1	0.51%
Hemothorax	6	3.05%
MI	1	0.51%
Respiratory failure	5	2.54%
Acute renal failure	1	0.51%
Total	19	9.64%

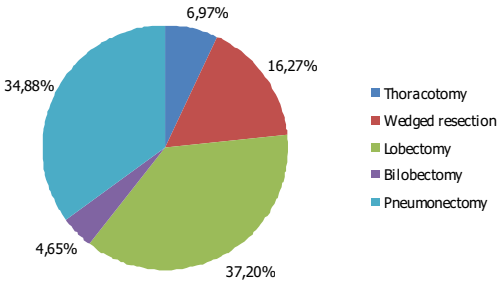

Fig. 10. Distribution of postoperative morbidity according to the type of intervention applied

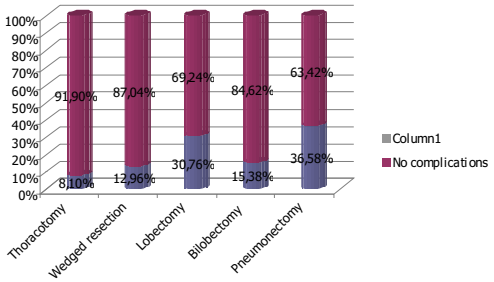

Fig. 11. The incidence of postoperative complications according to type of surgery

the FEV_1 value in patients deceased within 30 days postoperatively. We used as a standard the FEV_1 value of 60% of the ideal value. The FEV_1 ideal value is calculated based on age, sex and weight. Of the 8 patients who died, 5 (62,5%) had a FEV_1 on addmission over 60%, 3 patients (37,5%) had a FEV_1 under 60%. On the other hand, 4,76% of patients with FEV_1 over 60% died and and 3,26% of the patients with FEV_1 below 60% died. We did not obtained a statisticaly significant corelation between patient's death and the value of FEV_1 determined preoperative ($p=0.5943$).

We also did a review of the age of patients who died in the first 30 days postoperatively. In the group of the patients that died, the average age was 58.87 years, lower than the overall average of the lot which was 59.48 years. Of the patients who died, 6 were males (75%) and 2 were women (25%).

We also studied the correlation between overall mortality and type of surgery. Depending on the type of surgery, we recorded the highest mortality rates for patients who underwent lobectomy (3 cases – 1.52%); pneumonectomy (3 cases – 1.52%) and we recorded 3 deaths in patients who underwent exploratory thoracotomy (2 cases – 1.02%).

We studied separately the mortality rates for each type of surgery. The highest mortality was in patients who underwent pneumonectomy (3 cases – 7.31%).The mortality rate in patients who underwent lobec-

TABLE IV
The main causes of death

Cause of death	Nr. of cases	Percentage
Stroke	2	1.02%
Pulmonary embolism	2	1.02%
MI	1	0.50%
Respiratory failure	2	1.02%
Acute renal failure	1	0.50%
Total	8	4.06%

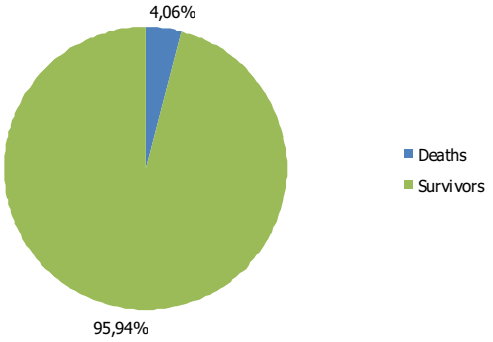

Fig. 12. Overall mortality rate

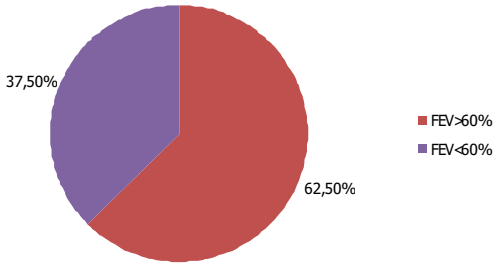

Fig. 13. Correlation between mortality and FEV's value

tomy was 5.76% (3 cases) and patients who underwent exploratory thoracotomy had a mortality rate of 5.40% (2 cases). In patients deceased following pneumonectomies, out of the 3 patients, 2 had a right pneumonectomy and 1 had a left pneumonectomy. There were no deaths in patients who underwent wedged resections or bilobectomy.

The analysis of deceased patients, in terms of associated diseases, revealed that the majority of patients had cardiovascular disease, diabetes or renal disease (2 cases of chronic renal failure). These patients usually had more than one associated diseases. We did not obtain a statistically significant relationship between mortality and associated diseases ($p = 0.2051$).

DISCUSSION

Thoracic surgery is engraved with increased morbidity and mortality. Therefore, a rigorous selection of patients undergoing such surgery is imposed. In order to establish the correct therapeutic attitude, paraclinical explorations are of the ulmost importance. The investigations of lung cancer patients serve a double purpose: both for diagnosis and for determining the surgical indication.

Laboratory examinations performed for the diagnosis of lung tumors used in our study were: chest X-ray, thoracic and abdominal CT scans, bronchoscopy. The remaining laboratory examinations were performed to determine the possibility and desirability of a surgical intervention.

ECG and echocardiography were used to diagnose possible cardiac co-morbidity. Echocardiography can detect neoplastic changes in the cavities of the heart and the major vessels of the heart which is a contradiction to surgery (T4 stage cancer). Chest CT can

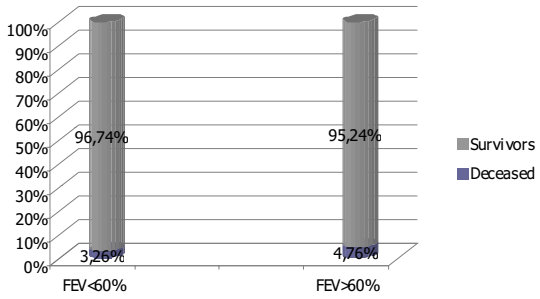

Fig. 14. Mortality rates according to FEV's value

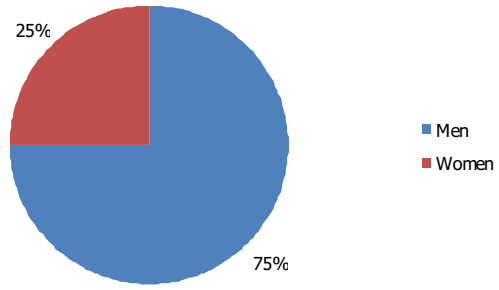

Fig. 15. Gender distribution of patients who died

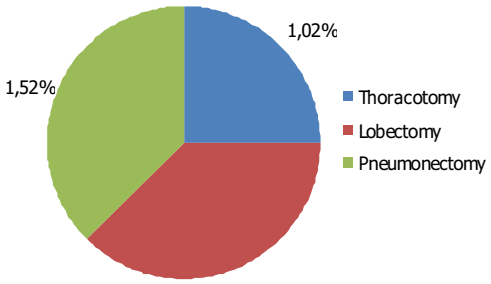

Fig. 16. Mortality rate by type of surgery

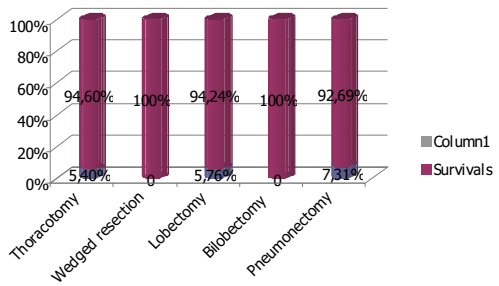

Fig. 17. Mortality rate by type of surgery

detect the invasion of major vessels, esophagus, distant metastases – also a contradiction to surgery (stage IV disease). PET-CT was only done in cases barely within the limit of surgery for a more accurate preoperative staging (1).

A central role in determining the surgical indication is occupied by ventilatory function tests. Olsen (1994) considers that operability of a patient can be established based on ventilatory function tests. For a patient to withstand lung surgery the FEV_1 must be over 60% of the ideal value and the FEV / VC ratio over 50% of the ideal.The ideal value is calculated based on age, sex, weight (2).

The majority of patients who underwent typical resection had a FEV_1 value of over 60% while the patients that underwent atypical resection had a FEV_1 value of below 60%. This difference is due to a rigorous selection of the patients that will undergo typical resection. On the other hand there were patients, who were in an operable state, but due to the low values of the ventilatory function tests, surgery with curative intent was not feasible, thus we opted for a wedged resection or an exploratory thoracotomy with biopsy. The ultimate goal of typical resections (lobectomy, bilobectomy and pneumonectomy) is practicing pulmonary typical resection combined with mediastinal lymphadenectomy.

There are 17 patients in our study who had a FEV_1 value of below 60% and yet typical resections were performed. 16 of these patients underwent lobectomy and 1 patient underwent a left pneumonectomy. For those 16 patients, surgery was performed due to their good clinical condition and the neoplastic disease was in it's infancy. The one patient with FEV_1 below 60% who underwent a pneumonectomy was out of necessity.

One of the most frequent complications after typical resections is the bronchial

TABLE V
Diseases associated to deaths

Associated diseases	Nr. of cases	Percentage
Stroke sequelae	3	37.5%
Diabetes	3	37.5%
Ischemic heart disease	3	37.5%
Hypertension	1	12.5%
COPD	1	12.5%
MI scars	2	25%
Chronic renal failure	2	25%

stump fistula. Bronchial stump fistula greatly increased the morbidity and mortality of these patients.

Regarding the postoperative complications, most of them occurred in males (88.37%) compared with just 11.63% in women. We place this discrepancy between sexes on the associations with cardiovascular disease. The higher incidence of atherosclerotic disease is well documented to be higher in males compared to women, especially in smokers.

76.74% of the patients who underwent typical resection had postoperative complications, while only 23.26% of the patients who underwent atypical resections had postoperative complications. This statistically significant association between the type of surgery and the postoperative morbidity is consistent with the literature data. Also, the highest postoperative morbidity rate was in patients that underwent pneumonectomy (36.58%), data are consistent with the literature.

The majority of postoperative complications, both major and minor were complications of the cardiovascular system and the respiratory system. These complications are to be expected in lung cancer surgery; the heavy smoker has a specific pathology which includes cardiovascular disease.

Morandi (1997) published a study on the occurrence of major postoperative complications after typical pulmonary resections, the incidence of these complications in their study was 9.64% (3). In the group we studied the incidence of these complications was 9.64%, slightly lower, probably because we studied patients with both typical resections, atypical resections and exploratory thoracotomy.

The average hospitalization duration is smaller for patient that underwent atypical pulmonary resection in comparison with patients that underwent typical pulmonary resection. These results are normal, atypical pulmonary resections are interventions with reduced morbidity and mortality compared with typical pulmonary resections; also the postoperative respiratory adaptation in much faster after an atypical resection. We obtained a lower mean duration of hospitalization when comparing bilobectomies with lobectomies because of the small number of bilobectomies (13 cases) compared to the lobectomies (52 cases). Morbidity was higher when lobectomies were practiced.

Achieving average length of hospitalization so high (16.84 days) shows that lung cancer surgeries are interventions with increased morbidity, increased financial costs to the health system and a longer term reintegration of these patients.

Pulmonary excision surgery is major surgery requiring a rigorous selection of patients (4,5).

A particularly important role in select-

ing patients is an accurate assessment of the ventilatory function tests. Not only the preoperative value is important as is predicting the postoperative value depending on the type of surgery performed. The FEV is regarded as the standard predictive risk factor for postoperative mortality in the literature (6,7).

FEV's importance as a risk factor for typical pulmonary resections manifests itself especially when pneumonectomies are performed. Understandably so, because these types of surgery, remove a far wider surface involved in haematosis.

In our study we did not obtain a statistically significant correlation between mortality and the value of preoperative FEV. A percentage of 4.76% patients with FEV over 60% died and 3.26% of patients with FEV below 60% died ; this diffrence is probably due to the fact that major surgery (typical pulmonary resection) was not performed on these patients.

Strand (2007), believes that another predictive factor in postoperative mortality is the patients age and type of surgery. The higher the age, the higher the postoperative mortality is, both because of the disease itself and because of co-morbidities. Typical pulmonary resections are associated with higher mortality and morbidity than atypical resections, especially right pneumonectomy (8).

In our study group, mean age of patients who died was 58.87 years, lower than the overall group which was 59.48 years. Our data are in contradiction with those published by Strand in 2007, probably due to the difference between the groups studied, associated pathology and different stages of the disease.

Instead we got a direct correlation between the sex of the patients and postoperative mortality, 75% of them were men, while only 25% were women.

We found a direct correlation in our study group between the type of surgery and the rate of mortality. We recorded the highest mortality rate in patients who underwent pneumonectomy (7.31%), followed by a 5.76% mortality rate in patients who underwent lobectomy.This is consistent with data published in the literature, various authors published a mortality rate after pneumonectomy ranging between 3.5% and 11.2% (9, 10,11).

Reviewing the literature, we found that typical pulmonary resections mortality varies between 2% and 12% . These relatively high differences are due especially to the size difference in the studied groups in each paper published. We obtained a mortality rate of 4.06% which is included in those obtained in literature.

We tried achieving a correlation between the rate of mortality and associated diseases ; the majority of patients had cardiovascular diseases and diabetes, but we could not obtain a statistically significant correlation between the two parameters.

Romano, in an article published in 1992, adds to the predictive factors with regard to postoperative mortality diabetes, ischemic heart disease and COPD (12). This is also true for our study.

CONCLUSIONS

Pulmonary excision interventions remain interventions with high mortality and morbidity. Pulmonary excision surgery is major surgery, so it requires a rigorous selection of patients that are undergoing such interventions. The vast majority of patients with lung cancer have numerous co-morbidities in addition to the respiratory disease. The main risk factors for postoperative complications are : late age, male gender, pneumonectomy, low FEV_1 value. Certain risk factors are predictive of postoperative mortality. The most important of them are : late age, male gender, type of surgery, FEV value, associated diseases (especially cardiovascular and diabetes).

ENDOSCOPIC VACUUM-ASSISTED CLOSURE (E-VAC) IN ACUTE MEDIASTINITIS FROM ANASTOMOTIC LEACKAGE AFTER INTRATHORACIC ESOPHAGEAL JEJUNAL ANASTOMOSIS (Abstract): Our aim was to assess the role of negative pressure therapy in the treatment of anastomotic leakage, after intrathoracic esophageal jejunal anastomosis by the evaluation of the time required for healing and the functional outcomes of patients. We present the case of a 73 years old male patient admitted in our clinic with esophageal perforation that appeared possible after a left thoracotomy necessary for an intrathoracic esophageal jejunal Roux-en-Y procedure, after a total gastrectomy for gastric neoplasm. There are groups that propose different approaches such as surgery variations or combinations of the surgery with or without adjuvant treatments, as the use of a hyperbaric chamber or vacuum devices such as Endoscopic Vacuum-Assisted Closure (E-VAC). Using a modified double-lumen naso-gastric probe adapted to the negative pressure unit and using the same principle as in the negative pressure treatment of soft tissue wounds we have achieved positive results with successful cure of esophageal perforation. The toraco-abdominal computed tomography done with contrast substance confirmed the esophageal perforation. The patient had a full recovery after 19 days of hospitalization with a positive check-up at one and two months after leaving our clinic. After the basic wound treatment, auxiliary methods such as negative pressure contributed to healing. Endoscopic vacuum treatment for parietal lesions of the esophageal wall is a great procedure in the management of this pathology with a high mortality and the surgeons and gastroenterologist must have considered as a treatment option in this kind of lessons. The prospective and comparative studies are necessary for the evaluation of this new and minim invasive procedure. **Keywords**: ENDOSCOPIC VACUUM-ASSISTED CLOSURE (E-VAC), ANASTOMOTIC LEAKAGE, INTRATHORACIC, ESOPHAGEAL JEJUNAL ANASTOMOSIS.

INTRODUCTION

Acute mediastinitis caused by bacterial infection due to esophageal perforation or sternotomy is a devastating disease which is frequently unresponsive to best medical therapeutic efforts, but if is diagnosed in its incipient state, and a well-planned treatment is instituted may favorably alter the prognosis (1).

Inflammation of the mediastinum may have several causes, among which are median sternotomy and esophageal perforation caused by Boerhaave's syndrome, dilatations or foreign bodies, as well as head and neck suppurations such as peritonsillar abscesses, deep cervical abscesses. Other less common causes include pleural empyema, osteomyelitis of the vertebrae and ribs, retroperitoneal abscesses and sub phrenic abscesses (2).

Although long recognized as a complication of certain infectious diseases, most cases of mediastinitis are associated with cardiac surgery (>300,000 cases per year in the United States). This complication affects approximately 1-2% of these patients (3).

The perforation of the esophagus is usually iatrogenic, from endoscopic procedures such as esophageal dilatation for strictures and for achalasia. It can also result from surgical interventions in close proximity to the esophagus. In about 15% of the cases, the rupture of the esophagus can be produce spontaneous without preexisting pathology. This is mostly related with intra-abdominal pressure from intense vomiting or severe retching, a clinic-pathologic entity originally called Boerhaave's syndrome. The same underlying mechanisms is involved in esophageal ruptures related to weight lifting, parturition, status epilepticus, defecation or to use of the Heimlich maneuver. Rare causes of perforation include external air-blast trauma and blunt trauma (4).

Another risk of esophageal perforation are deep neck infections of the oropharyngeal region. Delay in the diagnosis and treatment of deep neck infections may result in grave consequences. Once patients with this infection is complicated by descending necrotizing mediastinitis, one of the most disastrous complications, the mortality rate may be as high as 60%.

Conventional treatment of esophageal perforation is surgical. However, more recently, endoscopic treatment has become the treatment of choice given its less invasive nature compared to surgical treatment. This includes endoscopic clip administration, endoscopic stent placement, endoscopic suturing, endoscopic vacuum therapy and tissue sealants which are all administered via the endoluminal route. Whilst small defects (< 2 cm) may be closed with endoscopic clips, larger defects require stent placement or suturing. Removable esophageal stent is an effective method of treatment in cases with esophageal perforation as they allow minimal invasive repair of perforation and rapid nutrition. Endoscopic suturing can be used both to fix the stent to prevent migration and to primarily close the perforation. If perforation is associated with a mediastinal collection, drainage is mandatory, and this procedure can be performed by computed tomography guided percutaneous drainage, thoracoscopy or endoscopic vacuum therapy. In some cases, a combination of these minimally invasive methods is required. Since endoscopic methods provide better quality of life and outcomes and shorten length of hospitalization, such methods have become the treatment of choice for esophageal perforation (5).

Most surgeons believe that early diagnosis and invasive treatment are mandatory to effectively control the acute mediastinitis. Surgeons have not reached a consensus on the standard treatment protocol for such patients due to diversity in the causes and locations of infection. Some cases need surgical intervention, some kind of drainage or debridement. But the optimal technique of drainage and the most suitable surgical approach remain debatable (6).

Endoscopic vacuum-assisted closure (E-VAC) therapy is a new method for repairing defects of the upper gastro-intestinal system with different etiologies. This method has high success rates. E-VAC therapy consists of placing a sponge either within the lumen or within an abscess cavity connected with a nasogastric tube to a negative pressure system, thus decreasing bacterial contamination and edema and promoting granulation tissue proliferation, thereby gradually decreasing the cavity size until complete closure (7).

This method was developed in the early 1990s and is now standard of care for chronic surface wounds, ulcers, and burns. Adapting vacuum sponge therapy for use intraluminal for perforations of the esophagus was first reported in 2008 (8).

Required materials are a double-lumen naso-gastric probe, vacuum S size kit, surgical instruments for small surgery, and a vacuum pump.

Device preparation requires information about the size of the defect to be explored and also provides data for endoscopic guidance in preparing contact material (foam kit) and sizing the naso-gastric tube dimensions that will be mounted on the sponge. Obtaining the necessary data for the intervention is done by performing a CT scan (fig. 1).

The intervention involves a mixed endoscopic-surgeon-anesthetist team and the therapeutic gesture will take place in the surgery room, patient requiring general anesthesia with oro-tracheal intubation.

Fig. 1. The endoluminal vacuum kit.

Preparing the sponge according to the size of the cavity will be made respecting all three dimensions measured by the CT scan previously performed. The naso-gastric probe is adjusted according to the length of the sponge. The holes in the naso-gastric probe should not exceed the proximal and distal edge of the future sponge sleeve.

Perforated sponge is drilled by following an imaginary line through its center along its entire length, representing the future path through which the naso-gastric probe will be passed.

After preparing all this upper gastrointestinal endoscopy is performed with viewing the cavity of the wound, inspection and lavage.

The naso-gastric probe is passed through the nasal orifice and exteriorized through mouth, when the previously made sponge is attached with its firm anchorage. The endoscopist takes and drives the device created to the defect by placing it inside the cavity to be drained actively. The aspect of the assembly is visualized by the retraction of the endoscope and also under visual control is initiated the aspiration with negative pressure.

The endoscope is withdrawn, and the naso-gastric probe firmly fixed to the nose wing.

CASE REPORT

We present the case of a 73 years old male patient, which was admitted in our clinic with severe pain in the superior abdominal quadrant, lack of appetite, and loss of weight (about 20 kilograms in 10 months), eructation. From the personal pathological antecedents, we remember chronic hepatitis with C virus, chronic cardiac failure and mitral insufficiency. From the patient statement we understood that he was admitted in the Gastroenterological Institute with these symptoms, where the final diagnose was gastric neoplasia. We performed on the 2nd of November 2017 an exploratory laparotomy with adhesiolysis, total gastrectomy, DII lymphadenectomy and an intrathoracic esophageal jejunal anastomosis a la Roux-en-Y, pleural and multiple peritoneal and mediastinal drainage. In the first day after intervention the patient presented an anastomotic leakage on the esophageal jejunal anastomosis. A reintervention was performed with the suture of the fistula a mediastinal drainage. On the 10th day postreintervention the radiologic examination with opac index revealed a fistula tract on the left postero-lateral side of the esophageal jejunal anastomosis, fistula confirmed by the endoscopic and computed tomography examination.

We decided the minim invasive treatment - Endoscopic Vacuum-Assisted Closure (E-VAC) therapy on 17th of November 2017 and also, we performed a jejunostomy tube feeding, followed by the closure of the anastomosis defect thru inserting the E-VAC kit by superior endoscopy (fig. 2).

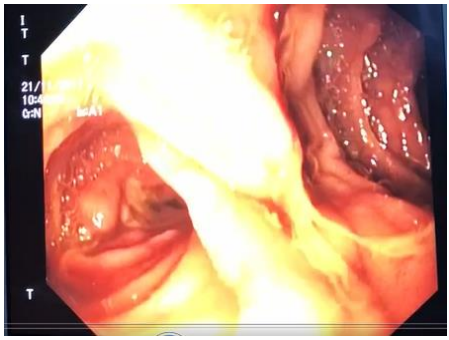

Fig. 2. Endoscopic initial aspect

We prepared the endoluminal vacuum kit (fig. 3) as we described before, with the

placement of the kit in the interior of the perforation following the description of the CT examination.

We set the device at a 165-mmHg pressure. The patient was motorized in the ICU Clinic for his biological status, enteral and parenteral feeding, and the good function of the vacuum kit (the washing of the kit to avoid the clotted of the secretions in the tube system).

We performed the change of the vacuum kit in the first state at 4 days after installing it, after that at 5 days under endoscopic control, with the checkup of the cavity that was smaller every time and the general status of the patient was better.

On post-operative day 19 the endoluminal vacuum kit was suppressed under endoscopic control, with complete healing (fig.3) which is also supported by the appearance of the superior digestive examination with opac index (fig. 4).

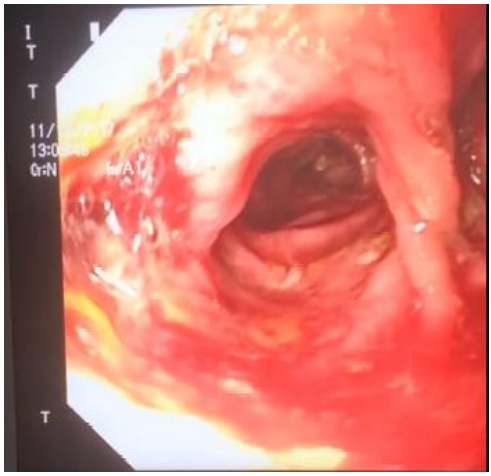

Fig. 3. Endoscopic control aspect

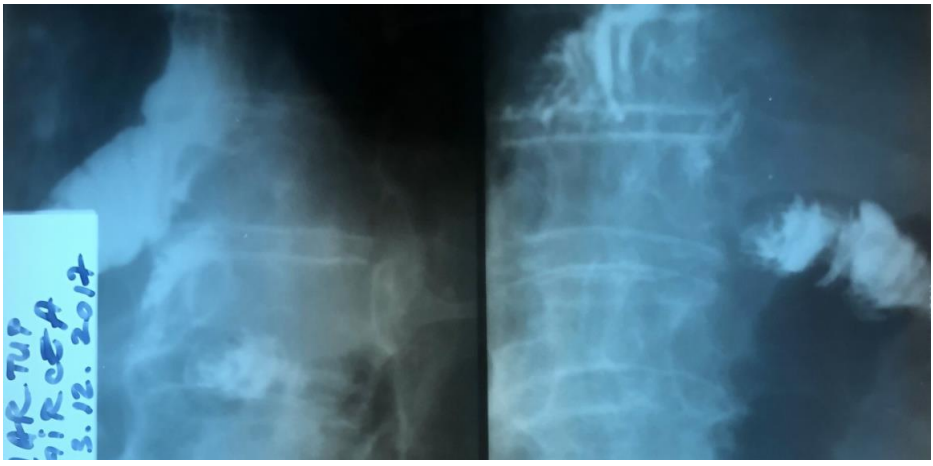

Fig. 4. Radiologic control aspect

DISCUSSION

Esophageal perforation is a rare and potentially life-threatening condition. Early clinical suspicion and imaging are important for case management to achieve a good outcome. However, recent studies continue to report high morbidity and mortality greater than 20% from esophageal perforation. At least half of the perforations are iatrogenic, mostly related to endoscopic instrumentation used in the upper gastrointestinal tract, while about a third are spontaneous perforations. Surgical treatment remains an important option for many patients, but a nonoperative approach, with or without use of an endoscopic stent or

placement of internal or external drains, should be considered when the clinical situation allows for a less invasive approach.

The rarity of this emergency makes it difficult for a physician to obtain extensive individual clinical experience; it is also challenging to obtain firm scientific evidence that informs patient management and clinical decision-making. Improved attention to nonspecific symptoms and signs and early diagnosis based on imaging may translate into better outcomes for this group of patients, many of whom are elderly with significant comorbidity (4). In a study performed on 17 patients with esophageal perforation the success rate of E-VAC to seal all esophageal perforations was 88% (8).

Endoscopic vacuum assisted closure is a new technique for the drainage of mediastinal collections. In acute esophageal perforation, appropriate drainage of the extra luminal contamination is necessary for a successful treatment modality.

Drainage procedure may be performed by open or minimally invasive surgery or interventional radiology. In addition to that, recently, E-VAC sponge system started to be used for the treatment of perforation as it was used to close soft tissue defects. While this approach is mainly used for chronic fistulas, it was also thought to be used for acute esophageal perforation (9). A study performed one 52 cases, 39 cases had anastomotic leakage, 13 cases had esophageal perforation, and 94% success rate was reported (10). Brangewitz *et al*. compared 39 patients who were treated using SEMP or SEPS with 32 patients who were treated with E-VAC for the treatment of intrathoracic esophageal leakage. This could be also correlated in some small degree with the latest interest of our group in a multidisciplinary approach on laparoscopic surgery and metabolic dysfunctions associated deficits (11-15), especially considering that esophageal perforation can be indeed associated with a multitude of other manifestations (16).

In a multi-variable analysis, successful wound closure was found to be independently associated with E-VAC treatment. The closure rate of the leakage in E-VAC group (84.4%) was found to be significantly higher compared to SEMS / SEPS group (53.8%) (17).

A study performed to evaluate the more effective therapy for the postsurgical gastro esophageal leakage by a head-to-head comparison of endoscopic vacuum therapy and endoscopic stent implantation with self-expandable metal stent, conclusion that vacuum is more effective and has fewer adverse effects than stent therapy as a treatment for postsurgical gastroesophageal leakage.

They believe that the advantages of vacuum therapy include a shorter median closure time, shorter hospital stay, and lower complications compared with stent therapy, which make it a potential alternative option for treating postsurgical gastroesophageal leakage (18).

CONCLUSIONS

Endoscopic vacuum treatment (EVT) for parietal lesions of the esophageal wall is a great procedure in the management of this pathology with a high mortality and the surgeons and gastroenterologist must have considered as a treatment option in this kind of lesions.

The prospective and comparative studies are necessary for the evaluation of this new and minim invasive procedure.

ACTUALITĂŢI ÎN TRATAMENTUL MEDICAL AL ENDOMETRIOZEI

R. Socolov, Şt. Buţureanu, Demetra Socolov, Allia Sindilar
Universitatea de Medicina şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină
Departamentul de Obstetrică-Ginecologie

MEDICAL TREATMENT OF ENDOMETRIOSIS. AN UPDATE (Abstract): Endometriosis is a major health problem, because of difficult diagnosis and limited therapies available. The surgical approach is done by very specialised surgeons, doing classical or laparoscopic ablative interventions. This article is an up-to date evaluation of medical treatment, reviewing the hormonal drugs (contraceptives, progestatives, GnRH analogues) and non-hormonal ones (anti-aromatase, anti-progestative, anti-tissular growth factors). The conclusion is that the medical treatment should be used in well selected cases, and adapted regimens, chossing among continuous contraceptives, intrauterine devices with levonorgestrel, or aromatase inhibitors. The main objective in this cases is rarely the complete cure, but more frquently optimal timing before surgery. **Key words**: ENDOMETRIOSIS, CONTRACEPTIVES, PROGESTATIVES, GNRH ANALOGUES

Endometrioza este definită ca implantarea de ţesut cu epiteliu glandular de tip endometrial şi celule stromale în afara cavităţii. Această localizare priveşte ovarele, peritoneul pelvin, şi trompele. În 75% din cazuri endometrioza externă afectează componente ale aparatului genital (uter, trompe, ovare, ligamentele largi, rotunde şi utero-sacrate). Restul de 25% din cazuri se referă la implicarea unor regiuni extragenitale intra şi extraperitoneale.

Această afecţiune reprezintă **o problemă majoră de sănătate** ea afectând circa 10-15% din femeile de vârstă reproductivă prin diversele sale manifestări (1). După Pauerstein, în fiecare an în SUA 4 femei din 1000 cu vârste de 15-64 ani sunt spitalizate pentru endometrioză.

CONDUITA CURATIVĂ MEDICAMENTOASĂ

Tratamentul endometriozei este în esenţă unul chirurgical, legat şi de diagnosticul afecţiunii, accesibil prin metoda endoscopică. Scopul acestui articol este de a revedea, pe baza dovezilor ştiinţifice existente, tratamentul medical.

Terapii neconvenţionale

O serie de abordări non-chirurgicale au fost enunţate în timp, având însă beneficii reduse sau chiar îndoielnice:

- Sarcina poate fi considerată ca un tratament hormonal natural, care ar determina clivajul mucoasei endometriale, inclusiv din focarele endometriozice
- aderenţele şi obstrucţiile endometriozice ale trompei pot fi desfăcute prin instilaţii utero-tubare, histerosalpingografie sau histeroscopie.
- Radioterapia- în scop de castrare- dar cu risc gebnetic, carcinogenic şi aderenţial semnificativ
- acupunctura, în şedinţe de 30 min, în puncte energetice specifice
- modificări ale regimului de viaţă: reducerea consumului de cafea, băuturi car-

bogazoase, ciocolată, ceai natural, zaharuri rafinate. Creşterea aportului de vegetale şi fructe, efortul fizic, înotul-ar fi factori protectivi.

- Radioterapia – în scop de castrare- dar cu risc genetic, carcinogenic şi aderenţial semnificativ
- Un studiu randomizat cu control (2) a arătat diminuarea dismenoreei şi hemoragiei, inclusiv în endometrioză de administrarea de vitamina E
- Electrostimularea, fizioterapia asociate cu acupunctura ar ameliora simptomele (mai ales durerea)- recom ESHRE guidelines 2008 categoria C (3)

Tratamente hormonale

Au fost propuse mai multe preparate cu componenţă sau efect hormonal :

- contraceptivele orale
- progesteronul, în formă clasică sau ca DIU
- antiprogestative
- modulatori ai receptorilor la progesteron
- danazol, antindrogenice
- analogi şi antagonişti de GnRH
- antiaromatazice
- agonişti de receptori beta de estradiol

a) Progestativele

Sunt printre cele mai frecvent utilizate medicamente în endometrioză.

Mecanismul de acţiune ar putea fi :

- decidualizarea endometrului, cu atrofie asociată
- efect anti ovulator dacă sunt administraţi în mod continuu, sau minim 20 zile/28, cu doze antigonadotrope
- contrabalansarea efectului promotor al factorilor de creştere determinat de estrogeni
- posibilă acţiune de inhibare a metalproteinazei matriciale endometriale, cu rol însemnat în timpul ciclului menstrual.

1) Acetat de medroxiprogesteron injectabil : meta-analiza Cochrane făcută de Prentice (4), arată, în puţinele studii cu control realizate, că există o eficienţă semnificativă pe durerile pelvine, lombare si legate de defecaţii ; efectele asupra infertilităţii par mai puţin importante.

2) Linestrenolul. Intr-un studiu complex făcut de Donnez (5) în care a utilizat linestrenol comparat cu alte regimuri (gestinone, danayol, buserelina spray sau implant) în endometrioze stadiu 3-4 postchirurgie, eficienţa a fost redusă, cu 80% leziuni încă active la 6 luni. Un studiu asemănător al lui Regidor (6) a arătat că tratamentul de primă intenţie rămâne cel cu antagonişti de GnRH, iar linestrenolul rămâne ca a doua opţiune, mai ales la tratamentele de lungă durată.

3) Didrogesteron (Duphaston). In aceeaşi meta-analiză Cochrane este citat un studiu în care utilizarea în faza luteală, după picul de LH, pe o durată lungă, a arătat un efect asupra durerii mai important doar la doze de 60 mg/zi, cu beneficii dipărute la un an de urmărire.

4) Acetatul de nomegestrol (Lutenyl) a fost analizat într-un studiu efectuat de Dorangeon (7) pe un număr mic de cazuri, iar rezultatele nu au părut semnificative statistic.

5) Acetatul de ciproteron (Androcur). Fedele a analizat într-un studiu mai vechi (8) comparativ un regim cu ciproteron acetat cu etinil estradiol (Diane 35 TM) faţă de danazol 600 mg/zi, 6 luni. Eficienţa asupra durerii a părut asemănătoare pentru cele două grupuri.

6) Utilizarea DIU cu levonorgestrel a făcut obiectul unui studiu al lui Vercellini (9), care a analizat efectul după tratament chirurgical asupra dismenoreei pe un lot cu DIU şi un lot cu placebo. La un an, dismenoreea apăruse într-un număr semnificativ mai mic la lotul cu DIU, iar autorii au concluzionat că inserţia imediat postchirurgicală a evitat recidiva dureroasă în o treime din cazuri. Un alt studiu (10) comparativ între eficienţa dispozitivului faţă de analogi de GnRH sugerează eficienţă asemănătoare asupra durerii, mai ales pentru stadiile mai

avansate de endometrioză. Aceleşi concluzii, de eficienţă pe durere în formele uşoare sau moderate, sunt citate de alţi autori. (11)

7) Modulatorii de receptori la progesteron (anti-progestative) se referă în principal la RU 486 (Mifegyne TM) şi Danazol. Dintre studiile existente asupra utilizării RU 486 în endometrioză, cel al lui Kettel (12) a arătat, pe un lot mic de 9 paciente, ameliorarea durerii pelvine, şi regresia focarelor în 55% din cazuri. Efectele secundare)menstre neregulate, sindrom de citoliză, hiperplaziile endometriale) limitează doza la 5 mg/zi, în timp ce autorii susţin că o doză eficace ar fi de peste 50 mg/zi.

b) Combinaţiile estro-progestative

Pornind de la constatarea că sarcina reduce simptomele şi limitează extensia endometriozei, a fost normal ca printre tratamentele hormonale încercate în endometrioză să se includă şi terapia estro-progestativă, datorită statusului pseudo-gestaţional indus de aceasta.

Mecanismul ar fi aşadar decidualizarea cu creşterea endometrului iniţial, iar ulterior o atrofie. Este vorba aşadar de activarea mecanismelor apoptozei pe care Meresman a demonstrat-o la o lună de la debutul tratamentului cu anticoncepţionale (13).

Literatura în acest domeniu nu este însă foarte vastă, şi meta-analiza efectuată de Moore şi colab pentru Cochrane database a găsit un singur studiu prospectiv randomizat controlat (14). Acest studiu a analizat tratamentul cu contraceptiv minidozat (20 gamma etinil estradiol) timp de 6 luni, comparat cu agonişti de GnRH, şi a constatat eficienţe asemănătoare asupra durerii şi dispareuniei, dar simptomatologia recidiva la 6 luni după întrerupere.

O variantă de terapie propusă mai recent este terapia cu contraceptive în regim continuu. Mahutte arată în studiul său o rată de satisfacţie a pacientelor sub tratament de 60-70%, asemănătoare cu alţi autori (15). Efectele secundare citate sunt prezente în 10% din cazuri: metroragii, senzaţie de balonare, greaţă, creşteri ponderale şi cefalee.

Recomandarea Colegiului American de Obstetrică Ginecologie (ACOG) în 2000 este că, faţă de abstinenţa terapeutică, tratamentul cu contraceptive este mai eficient în formele uşoare şi medii de endometrioză, fără a diferenţia între tipul ciclic şi cel continuu de administrare. In condiţiile lipsei de efect la 3 luni, recomandarea precizează necesitatea schimbării medicaţiei (16).

Agoniştii de GnRH

Efectul administrării agoniştilor de GnRH se exercită pe receptorul hipofizar pentru GnRH- cu iniţială creştere a eliberării de gonadotrofine, urmată apoi de o inhibiţie prelungită a secreţiei FSH şi LH, ca rezultat al desensibilizării celulelor gonadotrope la GnRH. Se vorbeşte de o castrare medicamentoasă reversibilă. Există diverse preparate disponibile, administrate pe cale subcutanata, intramusculara sau nazală: decapeptyl (Triptorelina), enantone (Leuprorelina), synarel (Nafarelina). Tratamentul uzual în endometrioză durează 6-12 luni, cu adăugarea din a 4a lună de "add-back therapy", reprezentat de estradiol şi progestativ.

Efectul agoniştilor a fost evaluat în numeroase studii, atât comparativ între ele, cât şi contra placebo, a danazolului etc.

Asupra infertilităţii, AFSSAPS citează 6 studii (17), în care tratamentul a durat 12--18 luni, fără diferenţe semnificative asupra numărului de sarcini obţinute faţă de pacientele cu abstinenţă terapeutică. Ca tratament preoperator, la czurile cu endometrioză cunoscută de stadiu 3-4, Audebert a arătat că scorul AFS s-a ameliorat semnificativ după 6 luni de tratament (18). Utilizarea postoperatorie pentru prevenirea recidivei a fost analizată de Busacca, într-un studiu randomizat cu control, la care concluzia a arătat că nu există un beneficiu clar al tratamentului postoperator cu leuproreline in administrare lunară (19).

Efectele adverse ale tratamentului cu

analogi de GnRH sunt :

- reacţii alergice, în general locale
- efecte de tip hipoestrogenie (bufee de căldură, cefalee, modificări de libido, dispareunie, instabilitate emoţională, astenie), chiar dacă necesită tratamente adjuvante, nu reprezintă motive de întrerupere a terapiei
- greaţă, vărsături, HTA, creştere ponderală, febră, anomalii de câmp vizual – rareori semnalate
- osteoporoza- pierderea de masă osoasă la 6 luni de tratament este de 10-25%, cu recuperare incompletă la oprirea terapiei

Rolul agoniştilor de GnRH în tratamentul infertilităţii şi pregătirea pentru FIV este disputat :

- Unii autori susţin o creştere de 4 ori a ratei sarcinilor obţinute prin FIV: (20, 21)
- Concluzii sunt discutabile din punct de vedere a metodologiei studiilor incluse în metaanaliză, a tipului de protocol asociat, a criteriilor de includere în studiu, a rezervei ovariene a pacientelor etc. (22)
- Alte studii susţin că endometrioza nu influenţează semnificativ succesul tehnicilor FIV (23)

Inhibitorii de aromatază

Celulele stromale endometriozice au o expresie excesivă a aromatazei P450, care converteşte sterozii C19 în estrogeni. Există autori care susţin că această anomalie se însoţeşte de un deficit de 17 steroid dehidrogenază, care inactivează estradiolul astfel rezultat, ceea ce favorizează suplimentar apariţia de implante endometriozice (24,25).

Preparatele de a treia generaţie a inhibitorilor de aromatază (anastrozol, letrozol) au o toleranţă bună. Anastrozolul (Arimidex) utilizat în cancerele de sân, a fost propus în studiul endometriozei de Ailawadji, timp de 6 luni, la paciente cu forme rezistente la tratamentul medico chirurgical. Scorul algic şi AFS a diminuat semnificativ la cele 10 paciente urmărite, dar bineînţeles că acest studiu trebuie extins în durată şi număr de paciente (26).

Antiinflamatoare nesteroidiene

Aceste medicamente sunt prescrise frecvent în dismenoree, iar cum multe cazuri sunt legate de endometrioză, a fost normal să fie evaluate în tratamentul acestei afecţiuni- în special al durerii.

Dintre preparatele recomandate de studiul AFSSAPS (17) citǎm :

- derivaţii de acid aril-carboxilic : acid tiaprofenic (Surgam TM), Ibuprofene (Nurofen TM), Ketoprofen - cu cea mai mare eficienţă
- Diclofenac, care a ameliorat semnificativ în studii randomizate simptomele dureroase
- acid mefenamic (Ponstyl TM, Vidan TM) este de asemenea eficient pentru dismenoree

Concluzia articolului menţionat este că antiinflamatoarele nesteroidiene trebuie recomandate de primă intenţie în tratamentul dismenoreei şi durerii abdomino-pelvine din endometrioză.

Danazolul

Derivat de 17 etinil-testosteron, danazolul are efect antigonadotrop la nivel hipotalamo-hipofizar ; de asemenea interferă cu mecanisme enzimatice ale steroidogeneză, crescând nivelul de testosteron plasmatic.

Efectul asupra durerii a fost demonstrat faţă de placebo, analogi de GnRH sau acetat de medroxiprogesteron. Sapte studii din literatură permit concluzia unei eficienţe asemănătoare cu analogii de GnRH, superioară celorlaltor terapii. Doza recomandată este 600-800 mg/zi, în medie 6 luni.

In privinţa numărului şi volumelor implantelor endometriozice, corelaţia între durerea ameliorată şi danazol nu a fost regăsită de unii autori. Deşi există o ameliorare a scorului AFS, eficienţa comparată cu analogii de GnRH este uşor mai mică.

Fertilitatea în urma tratamentului cu danazol nu a prezentat ameliorări semnificativ

diferite faţă de analogii de GnRH, coagularea chirurgicală, sau abstinenţa terapeutică.

Efectele secundare la dozele uzuale sunt semnificative. Este vorba mai ales de efecte androgenice : creştere ponderală, acnee, hirsutism, iritabilitate- în 12-28% cazuri, ca şi modificări ale metabolismului lipidic.

Alte direcţii de cercetare :

- Medicamente angiostatice, şi împotriva VEGF au arătat rezultate interesante experimentale, dar nu au fost studii umane (27).
- Unii autori susţin utilizarea modulatori selectivi de receptori progesteronici (28) – fără studii semnificative statistic : asoprisnil, CDB 4124 (proellex, progenta), PGL 4001 (ulipristal).

CONCLUZII

Tratamentul medical este încă subiect de cercetare şi nu există studii largi şi dovezi ştiinţifice care să confirme o terapie de elecţie. Nici terapia post-operatorie nu are un standard precis, iar situaţiile dificile (chist ovarian endometriozic bilateral la paciente cu infertilitate, endometrioza profundă extinsă la organe învecinate) nu au tratament de pregătire a intervenţiei chirurgicale cu scop curativ.

MULŢUMIRI

Acest articol este parte a cercetării efectuate în cadrul proiectului ID61/2007, finanţat de CNCSIS - cf contractului 343/ 1.10.2007.

DYNAMICS OF CLINICAL AND BIOLOGICAL ELEMENTS IN MECHANICAL BOWEL OBSTRUCTIONS–EXPERIMENTAL STUDY ON ANIMALS (Abstract): **Introduction:** the bowel obstruction represents a syndrome with significant clinical and biological modifications. **Material and methods:** we performed an experimental study on Wistar rats in which we induced a mechanical bowel obstruction. One group of subjects was used as control, on another group we ligated the sigmoid colon with surgical thread and on the last group we ligated a small bowel loop. **Aim:** our objectives were to analyze, in different time moments (after 2 days and 4 days, respectively, from the moment of obstruction), the clinical modifications (temperature, diuresis, neurological symptoms, body weight, abdominal circumference) or the biological imbalances (by monitoring the blood count, serum glucose, urea, creatinine levels). **Results:** the initial protocol could not be fully complied with, due to the premature deaths of a few subjects with bowel obstruction in the jejunum. From the point of view of the clinical features, we noted the occurrence of dizziness, reduction of the appetite and changes in diuresis in a number of subjects. We observed variations of abdominal circumference, temperature curve and body weight of the rats. We also determined modifications of biological parameters such as hemoglobin values, serum platelet count, glycemic values, serum urea and creatinine. **Conclusions:** the bowel obstruction leads to the installation of major clinical and biological imbalances, with the occurrence of major systemic disorders, finally leading to death in the absence of a quick, adequate treatment. **Keywords:** RAT, BOWEL, OBSTRUCTION, EXPERIMENT.

The bowel obstruction is a syndrome that occurs in approximately 20-30% of cases of acute abdomen encountered in surgical departments (1). Regarding me-

chanical bowel obstructions, they are characterized by important changes in the morphology of the digestive tract adjacent to the obstructive process, as well as alteration of the clinical parameters (2-13) and the installation of major biological imbalances (14-17).

Since patients usually do not present at the hospital when clinical manifestations occur, as well as the fact that the obstruction (especially in the case of tumors, adhesions or complicated abdominal wall defects) occurs progressively, it is difficult to establish a period of time between the installation of the pathological process and the determination of specific parameters.

We have thus outlined a study in which, using experimental animals, we can induce a mechanical bowel obstruction at different levels of the digestive tract, and afterwards, at well-established moments, to observe the changes that will occur, both clinically and biologically.

MATERIAL AND METHODS

The study was conducted within the "Cantacuzino" National Institute of Medico-Military Development Research, Băneasa Department, Preclinical Testing Unit, during a period of 5 days. The conditions for GLP (Good Laboratory Practice), in accordance to the OECD (the Organization for Economic Co-operation and Development) standards were respected, as well as the current Romanian laws and the internal protocols, with the authorization of the Veterinary Authority and Ethics Committee of the institute.

As laboratory animal we used the rat, Wistar strain, weighing between 150-200 g (grams) and between 6-8 weeks of age at the start of the study (fig. 1). We included in the study a number of 26 rats, both females and males, juveniles-adults, healthy, that had not been used in previous tests and whose source was represented by the Băneasa animal breeding department of the "Cantacuzino" Institute. Animal acclimatization was 8 days long and was performed under the same conditions as the study. The animals were housed in separate cages, made of polycarbonate, identified by a label indicating all the individual characteristics of the subject and the experiment, respectively, according to the internal protocols (fig. 2).

Fig.1-2. The Wistar rat used in the experiment and the individual cages

The ambient temperature was 18-24°C (Celsius), with a relative humidity of 30-70%, providing a 12-hour light/dark cycle. The animals were fed with standardized granulated fodder and drinking water, *ad libitum*, with no known contaminants that could have interfered with the results of the experiment.

The animals were divided into 3 groups, A, B, and C, each of them having 2 subgroups - A_1 and A_2, B_1 and B_2, and respectively C_1 and C_2, depending on the gender of the animal (tab. I). Group A was the control group consisting of 6 rats, group B was composed of 10 rats to which we induced a mechanical bowel obstruction in the large bowel, and group C was also composed of 10 rats to which we induced a mechanical bowel obstruction in the small bowel.

TABLE I
Distribution in the groups of the experiment

Group	Sub-group	Subjects' gender	Number of subjects /sub-group
A	A_1	Females	3
	A_2	Males	3
B	B_1	Females	5
	B_2	Males	5
C	C_1	Females	5
	C_2	Males	5

Ten hours (h) before the surgical procedure was performed, the animals were placed on an alimentary diet. General anesthesia of the animals was performed with a mixture of Ketamine (0.35 mg (milligrams)/kg (kilogram) of body weight) + Acepromazine (0.30 mg/kg of body weight), administered intramuscularly. Just before the procedure, performed at a moment we named T_0, a number of clinical parameters such as body weight, temperature (determined intrarectally), abdominal circumference (measured over the umbilicus), as well as laboratory assays such as blood count and serum creatinine, urea and glucose, were collected from each subject.

Blood sampling was made from the retroorbitary venous plexus under general anesthesia. Hematological determinations were made from blood sampled on EDTA (ethylene diamine tetra acetic acid) and the biochemical determinations were made from plasma obtained by centrifugation for 2 minutes at 4°C at 12,000 rotations per minute from blood sampled on heparin lithium.

At the T_0 moment, after collecting the above-mentioned parameters, the subjects in the control group (group A) were euthanized with an anesthetic overdose, each animal undergoing a complete necrotic examination.

For all the 10 subjects in the B group, a median incision was performed in the lower half of the abdominal wall. The muscular-aponeurotic layer was cut, entering the peritoneal cavity. The sigmoid loop was identified, placing a stenotic ligature with a 2.0 polyglycolic acid thread in the middle of the loop, without the involvement of the mezosigmoid, thus producing a mechanical bowel obstruction (fig. 3). Subsequently, the closure of the abdominal wall in a total layer was performed, using a 0 polyglycolic acid thread in surjet manner. The wound was toileted, and the subjects were placed in their respective cages.

In the case of the 10 subjects in group C, the surgical procedure was similar to the subjects in group B, with the difference that the incision was performed in the upper half of the abdominal wall and the ste-

notic thread was placed on a small bowel loop, without the involvement of the mesentery, at approximatively the junction of the upper third and lower two thirds of the jejuno-ileonum (fig. 4).

Following these procedures, each animal in groups B and C was closely monitored during the anesthesia recovery. In the next 3 days, each animal received anti-inflammatory (Ketofen, 3 mg/kg of body weight) and antibiotic (Enrodexil, 5 mg/kg of body weight) treatment, both administered intramuscularly, for the prophylaxis of postoperative infections and for the pain relief.

Fig. 3. Stenotic threads placed on the sigmoid colon

Fig. 4. Stenotic threads placed on the jejuno-ileonum

The initial study plans involved daily monitoring of the study subjects, recording the temperature, body weight, diuresis, as well as local or general clinical manifestations – loss of appetite or neurological disorders (agitation or dizziness).

Two days after the bowel obstruction was induced, at a moment we noted with T_2, it was desired to collect the biological parameters from the remaining subjects and measure their abdominal circumference, choosing randomly immediately afterwards a number of 5 subjects from each group, B and C, to be euthanized.

After another 2 days (4 days from the initial procedure, moment defined as T_4), it was hoped that the remaining 5 rats from each group would be subjected to similar procedures, with the dynamic analysis of the mentioned parameters, followed by the euthanasia of these last subjects, as well.

RESULTS

Compared to the initially established protocol, the viability for the subjects in group B was 100%, while for the subjects in group C it was 60%, given that 4 rats out of 10 from this group died before the scheduled time (2 rats at 48 hours, a rat at 53 hours and another one at approximately 61 hours from the onset of the experiment). So, concerning the subjects in group C, we had to overtake the initial plan and determine the parameters of the last 3 subjects from this group at 72 hours from the beginning of the experiment, in a moment we recorded with T_3, due to the alteration of their general condition and the estimation that they would not have survived until T_4 (tab. II).

In terms of clinical parameters, modified diuresis was found in 60% of subjects in both groups B and C, some of the rats

showing dizziness and reduction of the appetite. However, it needs to be mentioned that a quantifiable measurement of diuresis or feces weight could not be performed, as in the case of the blood pressure, which could not be determined.

TABLE II

Survival rate of the subjects in the experimental study

	Number of living animals at a given time (before the procedure from the respective day)				
Sub-group	**T_0 (onset of the obstruction)**	**T_1 (T_0 + 24h)**	**T_2 (T_0 + 48h)**	**T_3 (T_0 + 72h)**	**T_4 (T_0 + 96h)**
A_1	3	-	-	-	-
A_2	3	-	-	-	-
B_1	5	5	5	2	2
B_2	5	5	5	3	3
C_1	5	5	4	2	-
C_2	5	5	4	1	-

There were no problems with the abdominal wounds, no suppurations, seromas and we had no cases of evisceration.

The weight of the subjects, measured in grams, daily, is listed in the table below (table III) and represented in the following figure (fig. 5). For a better optimization, it was noted the average value of the subjects in each sub-group that remained alive at the time of the determination of the parameters, this principle being respected for the other numeric parameters that we will expose subsequently. Also, it must be noted that there were cases in which a sub-group was made up of a single subject at a given time.

Below, we present the temperature values of the studied sub-groups, mentioning that at the moment T_0 these values were measured under general anesthesia, as well as the fact that the normal temperature of the rat is between 35.9°C-37.5$^{0°}$C (tab. IV and fig. 6).

The values of the abdominal circumference of the subjects, measured in cm (centimeters), over the umbilicus, are shown below (tab. V and fig. 7).

We also represented graphically the dynamics of the average values of the hemoglobin (fig. 8,9), white blood cells count (fig. 10, 11) and the number of platelets (fig. 12, 13) in both groups B and C.

TABLE III

Variation of the average weight (in grams) of the subjects

Subgroup	T_0	T_1	T_2	T_3	T_4
A_1	182.33	-	-	-	-
A_2	189.66	-	-	-	-
B_1	189.00	196.46	183.54	178.35	180.18
B_2	186.00	198.45	185.82	189.32	183.11

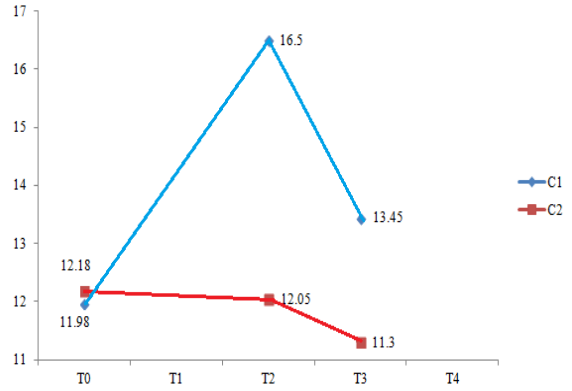

Fig. 9. Dynamics of the average values of hemoglobin (g/dL(deciliter)) in subjects from group C (unit reference values between 13.3-16.7 g/dL)

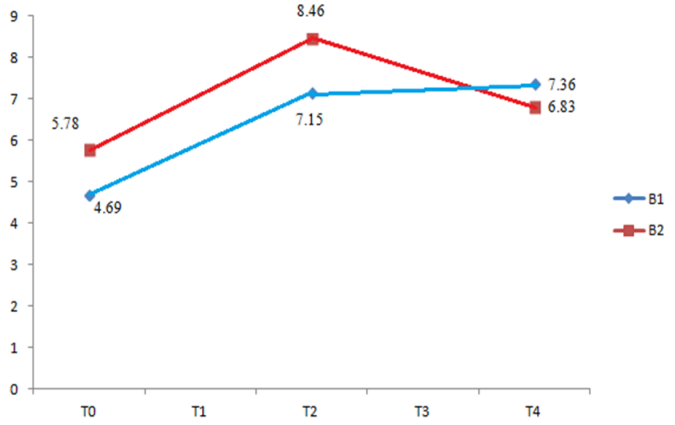

Fig. 10. Dynamics of the average values of white blood cells count (x 10^9/L (liter)) in subjects from group B (unit reference values between 3.27-11.14 x 10^9/L)

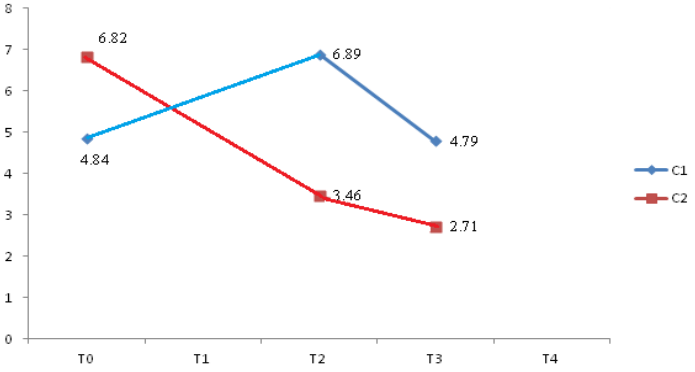

Fig. 11. Dynamics of the average values of white blood cells count (x 10^9/L (liter)) in subjects from group C (unit reference values between 3.27-11.14 x 10^9/L)

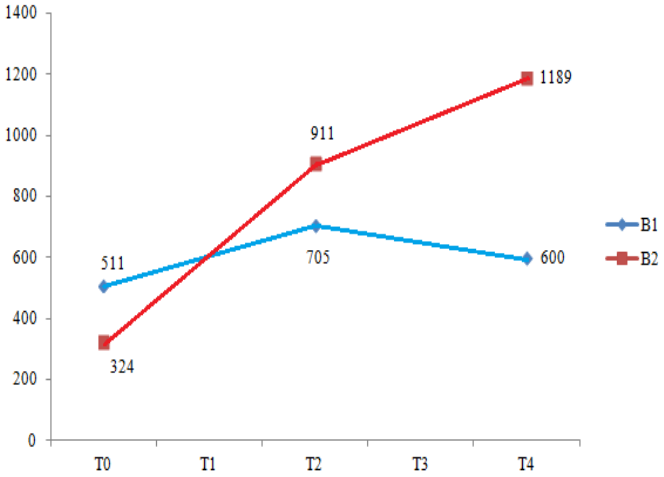

Fig. 12. Dynamics of the average values of the number of platelets (K (1000)/µL (microliter)) in subjects from group B
(unit reference values between 300-700 K/µL)

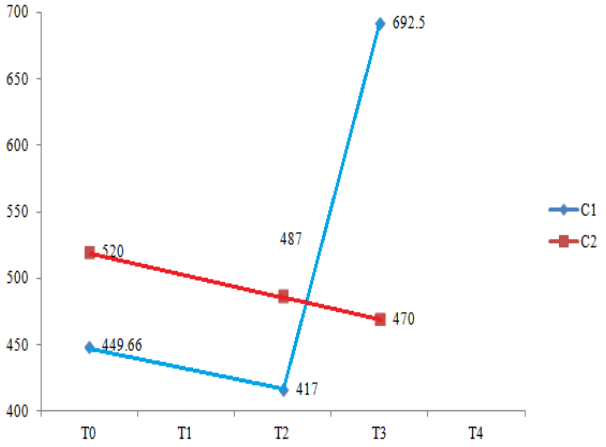

Fig. 13. Dynamics of the average values of the number of platelets (K (1000)/µL (microliter)) in subjects from group C
(unit reference values between 300-700 K/µL)

We also found a difference between the aspect of the blood plasma of the subjects in the B group, compared with that of subjects in group C, 48 hours after the induction of the bowel obstruction (fig. 14).

Regarding the biochemical parameters (blood glucose, urea, creatinine), we obtained the following values (tab. VI-IX), represented in the graphs below (fig. 15-20).

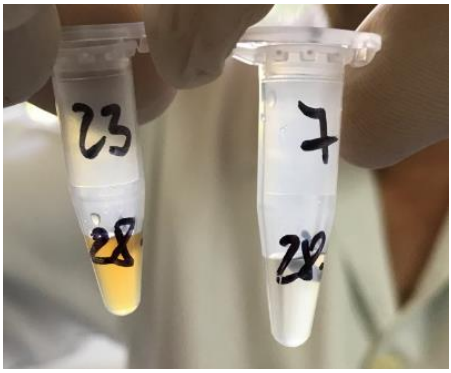

Fig. 14. The plasma aspect at the T_2 moment of a subject in group B (right, marked with 7) and a subject from group C (left, marked with 23)

TABLE VI

Average values of the biochemical parameters of the subjects in groups A, B, C, at the moments T_0, T_2, T_3 and respectively T_4

Parameter	Sub-groups						Unit reference values
	A1	A2	B1	B2	C1	C2

DISCUSSION

Clinical positive diagnosis of bowel obstruction is based on the specific symptoms (abdominal pain, abdominal distension, vomiting and stoppage of the intestinal transit), on the objective local examination of the patient as well on a series of extra-abdominal general signs (1), the latter being represented by cardiovascular features (tachycardia, hypotension), oliguria, fever or dehydration (13, 15).

In the bowel obstruction syndrome, a number of biological parameters such as metabolic acidosis, hexosaminidase, inorganic phosphate, serum amylase, intestinal fatty acid binding protein (I-FABP) or serum D-lactate were incriminated, their growth having been associated with an already established intestinal ischemia (18, 19). In the absence of these parameters, the usual biologic assays can highlight a number of changes in serum biochemistry, serum ionogram and blood count.

In terms of biochemistry, elevated glycemic values, as well as an alteration of renal parameters, with high levels of serum urea and creatinine, are often found, the renal failure worsening in the final stages of the bowel obstruction.

Hydro electrolytic imbalances are due to losses of sodium, chlorine and potassium ions. The kidneys try to compensate the hyponatremia by exchanging sodium ions with the potassium ions, amplifying the initial hypopotassemia. Subsequently, through hyper catabolism and tissue destruction, the hyperpotassemia occurs. As for the acid-base balance, by alkaline losses, usually a mixed acidosis is found.

In the case of the blood count, leukocytosis and thrombocytosis can be frequently found, while low hemoglobin may suggest a bleeding tumor in the digestive tract. Increased hemoglobin levels can occur in the case of hemoconcentration due to dehydration (14-17).

In the medical literature, a series of experimental studies have been published, that have analyzed changes in blood circulation, intraluminal pressures, bacterial flora multiplication, electrophysiological mechanisms or various imaging aspects using complete or incomplete intestinal obstruction models on different animals such as rats, dogs, cats, rabbits or pigs (20-34).

Regarding the subjects in our study, the protocol we imagined implied complete obstruction at various levels of the digestive tract (jejunum and sigmoid colon, respectively), monitoring dynamically a series of biological and clinical parameters, during several days.

However, this initial protocol could not be fully complied with, due to the premature deaths of a few subjects with bowel obstruction in the jejunum. Thus, after 3 days from the start of the experiment, we had to determine the parameters of the remaining living subjects in the respective group earlier, due to the severe alteration of their general condition and the improbability of their survival for another 24 hours.

From the point of view of the clinical features, we noted the occurrence of dizziness, reduction of the appetite and changes in diuresis in 60% of the subjects who were induced a bowel obstruction. It needs to be mentioned that due to some structural features of the diaphragm and the transmission of the nervous signals from the central level, the rat does not vomit (35).

The body weight of the rats determined dynamically revealed a decrease in values from the start of the experiment, this result being explained by the lack of food intake and dehydration of the subjects.

Temperature curve values showed an increase in the measured intrarectal temperature 24 hours after the obstruction, most likely in the context of the invasive surgical procedure. Subsequently, this parameter was normalized, the mechanism of the obstruction being a non-ischemic one, strictly to the digestive lumen, without the interest in the intestinal vascular supply and the subsequent possible onset of parietal intestinal necrosis.

The abdominal circumference also showed an increase of its values, because of the digestive tract distension located upstream of the obstacle.

Regarding the biological parameters, there was a slight increase in hemoglobin values as a result of dehydration, while the white blood cell count remained within normal limits. This latter parameter can suggest a lower rat systemic response to the obstructive process, taking also into account the effect of the anti-inflammatory treatment that was administered perioperatively in order to alleviate pain symptoms. The serum platelet count, in most subjects, showed an increase in the dynamic values, similar to the glycemic values, the latter most likely being explained by the unloading of the stress hormones into the blood stream. In addition, elevated levels of serum urea and creatinine suggested the occurrence of the renal failure with the progression of the obstructive syndrome.

CONCLUSIONS

The present experiment succeeded in inducing a mechanical bowel obstruction at different levels of the rat digestive tract (jejunum, respectively sigmoid colon), but the initial protocol, which involved the measurement of a series of clinical and biological parameters at well-established moments, required changes during the study due to premature deaths among subjects with jejunal topography, which suggests the higher severity of upper digestive obstruction.

From the clinical point of view, a number of changes were observed in the group of subjects, such as abdominal circumference increase, body weight decrease, dizzi-

ness, appetite decrease, ascension of the temperature curve in the first postoperative day, but there were also a number of parameters who were difficult to quantify (precise measurement of the diuresis volume, amount of feces or the blood pressure).

The biological features were represented by the increase of the serum values of hemoglobin, platelet count, glycemia and renal parameters.

Between the bowel obstruction in rats and humans there are a number of similarities regarding clinical (increased abdominal circumference) or biological parameters (increase of glycemic values, thrombocytosis, renal failure), but we have also encountered a number of animal-specific features in our study, such as the absence of vomiting or systemic leukocytosis.

The bowel obstruction leads to the installation of major clinical and biological imbalances, with the occurrence of major systemic disorders, finally leading to death in the absence of a quick, adequate treatment.

NUTRIŢIA ÎN COLESTAZĂ ŞI IMPACTUL PE TERMEN LUNG DUPĂ TRANSPLANT

Paula Popovici, Evelina Moraru
Universitatea de Medicină şi Farmacie "Gr.T. Popa" Iaşi
Facultatea de Medicină
Clinica a II-a Pediatrie

NUTRITION IN CHOLESTASIS AND LONG-TERM IMPACT ON TRASNPLANT (Abstract): **Aim**: Plurietiological hepatic cholestasis involves an increased risk of protein--caloric malnutrition and specifical nutritional deficiencies. Biological investigations to determine deficiencies in fat-soluble vitamins are essential for specific nutritional therapy . Although malnutrition is not an absolute contraindication for liver transplantation, its gravity has complex consequences in relation to this intervention. **Material and method**: The authors present a study conducted over a period of 5 years following the analysis of 293 children diagnosed with intra-or extrahepatic abnormalities that caused varying degrees of cholestasis. **Results**: In the study group, the percentage of infants with cholestasis was 45.39% (133 cases) and among them 62.12% had malnutrition (82 children). Clinical evaluation of fat-soluble vitamins deficiency, in particular, but also of the soluble and minerals was performed in all patients. Liver transplantation was successfully performed in three cases. **Conclusions**: Most important factors affecting growth after transplantation were age at the time of the liver transplant and primary diagnosis that required transplant. The role of nutritional support prior to liver transplantation is of great importance. Quality nutritional support change impact that malnutrition has on survival after liver transplantation. **Key words**: CHOLESTASIS, LIVER TRANSPLANT

Colestaza hepatică plurietiologică implică un risc crescut de malnutriţie protein--calorică asociind şi deficienţe nutriţionale specifice. Statusul nutriţional trebuie atent monitorizat în dinamică. Criteriile antropometrice convenţionale se pot utiliza cu mare dificultate şi nici nu au semnificaţia obişnuită în stadiul final al bolilor hepatice din cauza ascitei şi a edemelor, necesitând interpretări nuanţate (1,2).

Greutatea corporală este un parametru variabil în cadrul complicaţiilor bolii, iar creşterea ei poate chiar semnifica agravarea prin ascită refractară, edeme, hepatosplenomegalie, neavînd relevanţă specifică pentru malnutriţie. Talia poate aprecia gradul malnutriţiei cronice, fiind mai corect asociată perturbării nutriţionale. Dimensiunile pliurilor şi circumferinţa medie a braţului se modifică precoce în comparaţie cu talia, dar sunt influenţate de retenţia de lichide în zonele declive. Fluidele în exces se acumulează decliv şi de aceea trebuie notate dimensiunie pliurilor în 1 superioară a corpului (3).

Investigaţiile biologice pentru determinarea deficienţelor în vitamine liposolubile sunt esenţiale în monitorizarea biochimică în scopul terapiei nutriţionale nuanţate. Mecanismul major implicat în apariţia malnutriţiei îl reprezintă diminuarea concentraţiei de acizi biliari secundară scăderii fluxului biliar. Colestaza determină reducerea semnificativă a absorbţiei lipidelor şi a trigliceridelor cu lant lung, care la rândul lor determină reducerea balanţei energetice şi malabsorbţia vitaminelor liposolubile (4).

În stadiile finale ale bolilor hepatice cro-

nice malnutriţia este o regulă. Deşi malnutriţia nu reprezintă o contraindicaţie absolută a transplantului hepatic, gravitatea ei are consecinţe complexe în relaţie cu această intervenţie în evoluţia imediată postoperatorie, complicaţiile precoce, statusul vital pe termen lung, calitatea vieţii.

Există numeroase riscuri pe termen lung pentru deteriorare nutriţională şi metabolică la copiii cu transplant hepatic. Principiul de bază în tratamentul deficitului nutriţional din cadrul colestazei este de a corectă statusul nutriţional astfel încât să se poată preveni deficienţele nutriţionale (5).

Instalarea progresivă a malnutriţiei creşte riscul de morbiditate şi mortalitate, explicat de faptul că sindroamele de deficienţă sunt refractare chiar şi la măsuri terapeutice de mare complexitate. Ameliorarea statusului nutriţional este o verigă importantă pre şi posttransplant hepatic. Terapia nutriţională trebuie aplicată indiferent de dificultăţile şi reversibilitatea unor manifestări.

MATERIAL ŞI METODĂ

Studiul efectuat a fost atât retrospectiv (în perioada 01 ianuarie 2005- 01 noiembrie 2006), cât şi prospectiv (01 noiembrie 2006--31 septembrie 2009), analizând copiii internaţi în această perioadă în Clinica a II-a Pediatrie a Spitalului Clinic de Copii „Sf. Maria" Iaşi pentru diverse afecţiuni posibil generatoare de colestază intra- sau extrahepatică.

Criteriile de includere în studiu a pacienţilor au fost :

- Vârsta cuprinsă între 0-18 ani
- Confirmarea colestazei
- Confirmarea patologiei generatoare de colestaza prin mijloace biologice si imagistice, analizand ulterior rezultatele pe categorii etiologice conform unei clasificari prestabilite.

Astfel au fost evaluaţi 293 copii diagnosticaţi cu anomalii intra- sau extrahepatice ce au determinat diverse grade de colestază. Lotul de studiu a fost subdivizat în două mari grupe :

I. Situaţiile clinice ce au determinat *obstrucţie extrahepatică* au reprezentat 10,23% din cazuri fiind reprezentate astfel :

- Litiaza biliară - 18 cazuri (60%)
- Atrezie căi biliare extrahepatice - 8 cazuri (26,6%)
- Chist de coledoc - 4 cazuri (13,4%).

II. Patologia intrahepatică a fost întâlnită cu o frecvenţă mai mare (89,77%) decât cea extrahepatică şi a fost grupată astfel :

- Cauze infecţioase - citomegalovirus (87 cazuri), toxoplasma (32 cazuri), cauze infecţioase-toxice cu endotoxemie-sepsis, infecţie urinară cu *Escherichia coli* (8 cazuri).
- Cauze metabolice- fibroza chistică (46 cazuri), hipotiroidie (14 cazuri), boala Wilson (12 cazuri) , glicogenoza tip I (3 cazuri), boala Gaucher (2 cazuri).
- Hepatita neonatală idiopatică - 26 cazuri.
- Displazia arterio-hepatică (sindromul Alagille) - 9 cazuri.
- Cauze anatomice (chist hepatic) - 8 cazuri.

REZULTATE ŞI DISCUŢII

Relaţia între boala hepatică şi gravitatea malnutriţiei se corelează în special cu vârsta mică. Peste 60% dintre sugarii cu boli hepatice colestatice au malnutriţie după studiile lui Sokol şi Stall (6). În lotul studiat, procentul sugarilor cu colestază a fost de 45,39% (133 cazuri) iar dintre aceştia, au prezentat malnutriţie 62,12% (82 copii) (fig. 1).

Evaluarea clinică a deficitului vitaminelor liposolubile, în special, dar şi a celor hidrosolubile şi a mineralelor s-a efectuat la toţi pacienţii şi s-au obţinut următoarele rezultate :

- Deficitul de vitamina A – 84% dintre copiii cu colestază prezentau pielea uscată.
- Deficitul de vitamina D - a fost monitorizat prin urmărirea semnelor clinice dar şi paraclinice (biologice şi radiologice) de rahitism, prezent în special la sugari

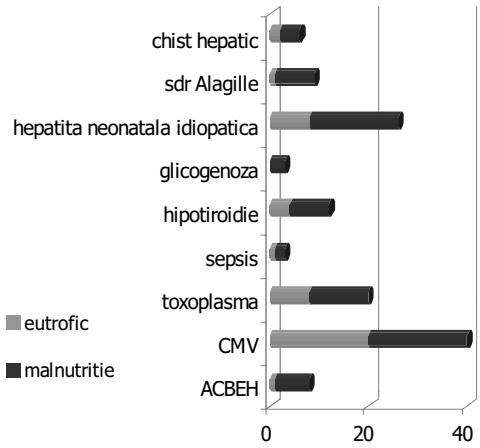

Fig. 1. Repartiţia cazurilor de malnutriţie în lotul sugarilor cu colestază

(66%), evidenţierea osteopeniei la densitometria osoasă (38%), hipotonia musculară (9%), fracturi pe os patologic (3 cazuri) - fig 2.

- Deficitul de vitamina E- a fost mai rar întâlnit în lotul studiat (3%) iar determinarea serică a alfa-tocoferolului nu a putut fi realizată.
- Deficitul de vitamina K - nu a avut un răsunet major în tabloul clinic al copiilor cu colestază însă a fost demonstrată biologic prin alungirea timpului Quick şi a timpului de protrombină în 71% din cazuri.
- diverse grade de anemie au fost întâlnite la majoritatea copiilor cu colestază (85%), aceasta datorându-se mai multor factori secundari malabsorbţiei induse de colestază (deficit de acid folic, vitamine B_1, B_6, B_{12}, fier)

În ceea ce priveşte terapia nutriţională a acestor copii scopul este de a asigura un aport caloric de 130% din aportul caloric zilnic recomandat de vârstă. Dacă acest scop nu este atins prin hrănire pe cale orală, hrănirea pe sondă nasogastrică ar trebui luată în considerare, furnizând o cantitate suficientă pentru a ajunge la 150 Kcal / kg / zi (4). Aceste măsuri ar trebui să fie luate imediat ce se observă o întârziere în creşterea ponderală pentru a putea preveni instalarea malnutriţiei.

Fig. 2. BR, atrezie de căi biliare extrahepatice

Astfel, copiii cu malnutriţie din lotul studiat au beneficiat de o dietă individualizată, administrată pe cale preponderent enterală, încercându-se suplimentarea variatelor deficienţe, urmărind câteva principii :

- menţinerea unui aport caloric şi proteic crescut (2,5 - 3 g/kg corp/zi)
- conţinut ridicat de calorii : 0.8 - 1 Kcal / ml (Dextrine maltoză, 60% din aportul energetic)/ caloriile necesare depăşesc 130 – 150% din raţia recomandată pentru greutatea totală, ajungînd la 150 – 200 cal/kg /zi
- dietă îmbogăţită cu aminoacizi cu lanţ ramificat (0,25 g/kg/zi)
- glucide -15 – 18 g/kg/zi , administrat sub formă de polimeri de glucoză
- lipide 8 – 9 g/kg/zi (15% trigliceride cu lanţ mediu)
- creşterea conţinutului de vitamine liposolubile
- acizii grasi esenţiali
- conţinut scăzut de sodiu, cupru şi conţinut ridicat de zinc întrucât enzimele esenţiale în funcţionalitatea hepatică necesită cofactori de activare reprezentaţi de oligoelemente
- raportul calciu / fosfor = 2

În ceea ce priveşte terapia deficitelor în vitamine liposolubile şi minerale, dozele au fost stabilite după următoarele formule :

- Vitamina K : - 1 mg/kg, maximum 10 mg, intra-muscular, o dată la 1-2 săptămâni
- Vitamina E : - 10 mg/kg, IM, la fiecare 2 săptămâni/ 25 UI/kg, oral
- Vitamina A : - 25000 - 50000 UI, IM, o dată pe lună
- Vitamina D - 30000 - 60000 UI, IM, o dată pe lună
- Calciu : - 50 mg/kg/zi, oral
- P : 25 mg/kg/zi, oral
- Zinc : - 1 mg/kg/zi, (zinc sulfat), oral

În multe cazuri cu boală hepatică terminală la copil, numai transplantul hepatic reprezintă o modalitate efectivă de tratament. În funcţie de starea pacientului, pediatrul trebuie să decidă dacă este momentul optim pentru transplant hepatic astfel încât statusul nutriţional să nu fie un impediment pentru realizarea transplantului. Obiectivul major este ca pacientul să fie preluat de echipa de transplant hepatic într-o stare nutriţională care să permită avansarea unui prognostic evolutiv bun posttransplant (7,8).

În lotul studiat, transplantul hepatic s-a efectuat cu succes în trei cazuri – doi băieţi cu sindrom Alagille şi o fetiţă cu atrezie de căi biliare extrahepatice. Vârsta efectuării intervenţiei chirurgicale a fost în medie de 2 ani în toate cele trei situaţii. Statusul nutriţional în cazul fetiţei cu atrezie de căi biliare extrahepatice a fost normal atât precât şi posttransplant. În situaţia copiilor cu sindrom Alagille, aceştia prezentau o malnutriţie protein calorică gradul I în momentul efectuării intervenţiei chirurgicale, menţinând şi în prezent, (la 3, respectiv 4 ani posttransplant) hipotrofie staturoponderală.

Conform rapoartelor anuale prezentate de SPLIT (studii despre transplantul hepatic la copil), aproximativ 20% din beneficiarii unui transplant hepatic menţin un retard al creşterii după transplant. Se consideră că o creştere nesatisfăcătoare pretransplant nu poate fi corectată complet deşi un procentaj mare de copii recuperează deficitul staturo-ponderal (9,10).

S-a observat că în situaţia celor doi copii cu sindrom Alagille ce au beneficiat de transplant hepatic, retardul ponderal s-a accentuat iniţial, în primele 6 luni posttransplant, pentru ca ulterior, curbele ponderală şi staturală să evolueze ascendent ; în ambele situaţii, curba staturală se menţine în jurul valorii de -2DS, în timp ce curbele ponderale se situează în jurul valorilor de -1 DS. Pentru prevenţia şi terapia încetinirii creşterii, copiii pot beneficia de administrarea hormonului de creştere recombinant.

Potrivit aceluiaşi raport, factorii cei mai importanţi care afectează creşterea dupaă transplant sunt vârsta în momentul efectuării transplantului (pacienţii cu vârsta sub 2 ani au avut cea mai mare creştere), scorul Z la transplant, şi diagnosticul principal ce a impus efectuarea transplantului (pacienţi cu atrezie biliară par să aibă cele mai bune recuperări ale creşterii). Astfel, studiul de faţă, deşi pe un număr mic de pacienţi, susţine ideile mai sus menţionate (11,12,13).

CONCLUZII

Malnutriţia protein-calorică în patologia hepatică reprezintă un aspect dramatic care poate fi prevenit printr-un program individualizat fiecărui caz.

Suportul nutriţional scade morbiditatea prin infecţii (în special datorate deteriorării imune din malnutriţie şi agravate de imunosupresia posttransplant), asigură necesarul metabolic disponibil funcţiilor de sinteză, stocaj şi detoxifiere a ficatului grefat, scade mult rata complicaţiilor chirurgicale, asigură creşterea lineară, dezvoltarea mentală şi previne osteopatia metabolică.

Rolul suportului nutriţional premergător transplantului hepatic este de mare importanţă. Asistenţa nutriţională de calitate modifică impactul pe care malnutriţia îl are asupra supravieţuirii după transplant hepatic. Creşterea normală posttransplant este

un indiciu al funcţionalităţii grefei, dar un discret deficit în talie se menţine câţiva ani în orice condiţii.

Evaluarea necesită, de asemenea, măsuri speciale iar corecţia trebuie adaptată fiecărui caz, metode clasice de aport caloric fiind contraindicate în cazurile cu hipertensiune portală.

Evaluarea nutriţională permanentă, terapia nutriţională eficientă şi reală necesită o pregătire de specialitate, suport material şi logistic, o bună colaborare interdisciplinară, echipe de nutriţionişti care să colaboreze permanent cu echipa de transplant.

EPIDEMIOLOGICAL CONSIDERATIONS ON POLYTRAUMA IN CHILDREN AND ADOLESCENTS (Abstract): Polytrauma is a major public health problem and a leading cause of death and disability for children at any age. **The study aim** was to identify the factors which influence the lesion trauma model and can be a starting point in setting the strategy for approaching violent accidents in children and young people. **Material and methods**: The descriptive study was carried out on a group of 1532 patients with polytrauma, admitted in the Emergency Department (ED) of the "Sf. Ioan" Children's Emergency Clinical Hospital, Galati, Romania, during 2012 - 2016. The data were analyzed using the *SPSS V.24* software. **Results**: Road traffic accidents encountered the highest incidence (54.9% - 841 cases). The mean age was 9.4 ± 4.32 SD. An increased frequency of urban cases (53.46%) – and males (67.49%) were highlighted. The comparative analysis of the monthly incidence showed a significantly higher incidence during August (13.3%). The distribution of cases by days of week noted an increased incidence in Sunday (21.1%). **Conclusions**: Characteristics of the case that may be admitted more frequently in our ED were those of a 9-year-old child, most likely male, from rural area, with polytrauma due to a road traffic accident that occurred more frequently in summer at the weekend. Our study could be useful for a better medical and prevention management of polytrauma at pediatric age. **Keywords**: EMERGENCY DEPARTMENT, POLYTRAUMA, EPIDEMIOLOGY, CHILDREN.

Polytrauma continues to be a main cause of death and disability in all age groups, especially in young people. The first assessment and management of seriously injured patients is a difficult task and requires a rapid and systematic approach. This systematic approach can be used to increase the speed and accuracy of the evaluation process, but a good clinical assessment is also required. The term of polytrauma defines a severe acute condition that occurs following an accident due to a physical or a chemical aggression, characterized by the presence of multiple lesions affecting body organs or systems. Polytrauma due to road traffic accidents is the main cause of mortality in people aged between 1-40 years. Deaths due to polytrauma in children aged of 1-15 years exceed all other causes counted together, and they are only the tip of the iceberg because for 1 deceased child, 2 children remain with disabilities, 34 children require long-term hospitalization, and 30 children are check out in emergency rooms and outpatient units (1, 2).

Approximately 1.35 million people die

each year due to road traffic accidents. The 2030 Agenda for Sustainable Development set an ambitious target of halving the overall number of deaths and injuries caused by road traffic accidents by 2020. Road traffic hazards are the main cause of death for 5-29-year-old children and adolescents. Data for Romania show that in 2016 there were 1913 road traffic accidents, 73% in men and 27% in women, with a fatality rate estimated by the WHO at 10.3% of 100,000 inhabitants (3).

A recent report (4) from 34 countries showed that more than 8,100 children died in road traffic accidents in the last decade in the European Union. In 2016, a number of 630 children died in a traffic accident. In the EU, 46% of all road traffic deaths occur on rural roads, 46% on urban roads and 7% on highways. In Romania, about 74% of all road traffic deaths occur on urban roads, as compared with 67% in Croatia or 64% in Serbia. Although the incidence of polytrauma in children has decreased in EU22, by 4.6% annually, from 2006, in Romania, the number of children injured in road traffic accidents increased by almost 2% each year.

The aim of the study was to identify the factors which influence the lesion trauma model and can be a starting point in setting the strategy for approaching violent accidents in children and young people.

MATERIAL AND METHODS

The present descriptive study was carried out on a group of 1532 patients with polytrauma, admitted in the Emergency Department (ED) of the "Sf. Ioan" Children's Emergency Clinical Hospital, Galati, Romania. The study was performed retrospectively between 2012 and 2016.

Statistical analysis

The data were analyzed using the *SPSS V.24* software (IBM Statistical Package for Social Sciences, Chicago, Illinois). Student t test, Pearson-χ^2, Fisher's test, Levene's test, ANOVA test, and Pearson linear regression were used. The descriptive statistical indicators (mean, standard deviation, standard error, minimum, maximum, and quartile intervals) were calculated for continuous variables. In the descriptive statistics we calculated the values of the localization indicators (mean, median, mode values), spreading (dispersion, standard deviation, amplitude), we determined, where appropriate, the 95% confidence interval for the study of proportions. In the statistical analysis we applied tests to determine the regression model or Chi square test (χ^2) to compare the proportions. The calculation of the intervals of variation of the statistical indicators as well as the statistical hypothesis testing was performed with the 95% confidence interval and a significance threshold of p-value = 0.05.

RESULTS

Patients with polytrauma of various etiologies were evaluated and stabilized in the ED, followed by specific treatments by admission or transfer of patients to other units. The casuistry analysis (n = 1532) showed an increase in the frequency of cases from 272 patients recorded in 2012 to 396 cases registered in 2016 (fig. 1).

It is noteworthy that among polytrauma cases admitted in the ED, road traffic accidents encountered the highest incidence (54.9% - 841 cases). A high frequency has also polytrauma caused by falls from height (23% - 353 cases). A frequency of less than 10% was found for polytrauma caused by hetero aggressions (8.6%), bicycle / scooter accidents (6.1%), accidents caused by carts (4.6%) (tab. I).

The age of polytrauma cases was between 0 and 18 years, according to the specialty of the hospital, with a maximum of accidents recorded in 9-year-old patients (fig. 2). The mean age was 9.4 ± 4.32 SD. Quartile intervals indicated that 50% of cases were less than 10 years of age, and 25% under the age of 6 years. The value of quartile 3 indicated that 25% of cases were aged of 13-18 years.

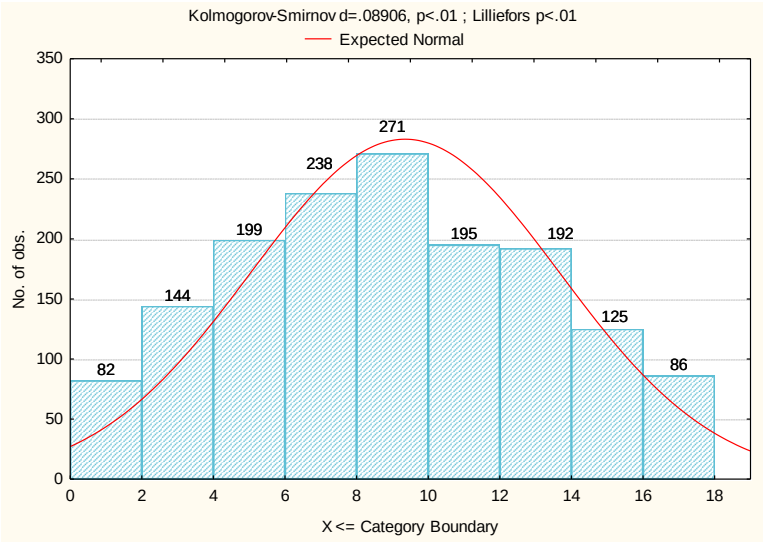

Fig. 2. Age histogram

The analysis of demographic characteristics regarding *residence area* revealed an increased frequency of urban cases 53.46% (p = 0.046) compared to those from the rural area (46.54%).

The distribution of cases by gender indicated that 1034 were males (67.49%) and 498 females (32.51%), with a statistical significance (p = 0.0027, 95% CI) of polytrauma among male patients (tab. II, III).

TABLE II

Demographical characteristics

Demographical characteristics		n	%	p (Chi-square test –95%CI)
Gender	Male	1034	67.49%	0.00274*
	Female	498	32.51%	
Residence area	Urban	819	53.46%	0.0463
	Rural	713	46.54%	
Total of cases		**1532**		
(*) p <0.05 – significant differences				

TABLE III

Statistical indicators: age in relation with patients' gender

Gender	Age average	Mean		Std. Dev.	Std. Err.	Min	Max	Q25	Median	Q75
		-95%	+95%							
Male	9.43	9.16	9.69	4.31	0.13	0.29	18.00	6.00	10.00	13.00
Female	9.20	8.82	9.59	4.34	0.19	0.36	18.00	6.00	8.00	13.00
Levene test: F=2.4702, p=0.1162; ANOVA: F(1,1530) = 0.8911, p = 0.3453										

The seasonal evolution of cases revealed significant differences in the frequency of according to the calendar months (fig. 3). The comparative analysis showed a significantly higher incidence during the summer months (July - 10.9%, August - 13.3%). A small incidence was found for December (5.4%) and January (4.4%). The incidence was significantly influenced by the calendar seasons (χ^2 = 21.56, p = 0.002, 95% CI), being increased in the summer season (34% of total cases).

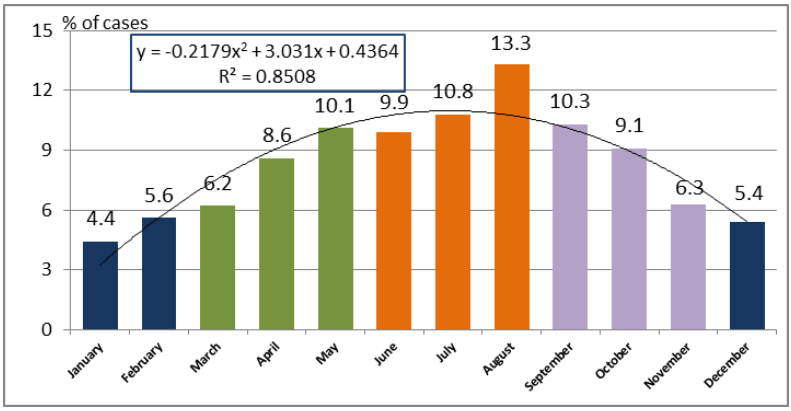

Fig. 3. Monthly incidence of polytrauma cases

The distribution of cases by days of week noted an increased incidence in weekend days, Friday (14.6%), Saturday (19.7%), and Sunday (21.1%). The smallest incidence of polytrauma cases was found on Wednesday (10.2%), but close values were encountered for Monday (11.9%), Tuesday (11.2%), and Thursday (11.2%). The association of the polytrauma cases frequency with the weekdays was statistically significant (χ^2=17.53, p=0.0396, 95% CI) (tab. V, fig. 4).

DISCUSSION

According to annual WHO reports, approximately 200,000 deaths among children were registered due to road traffic accidents. Trauma due to road traffic accidents, by their very high incidence, represents a major public health problem worldwide. Due to their age-specific peculiarities, children are a population at high risk for trauma, in general, due to their capability of attention, perception, and discernment involved in producing events with vital risk (5, 6).

There are differences in the frequency of gender-related polytrauma starting from the first year of life. Frequency of polytrauma is similar up to 5 months of life, with differences occurring when the child begins to walk. The difference is progressively accentuating with a maximum in adolescents, the risk of death caused by polytrauma being higher in boys. The gender differences in incidence are attributed to behavior, risk exposure by games or sports activities (7, 8).

Urban and rural areas have notable differences, and serious road traffic accidents involve mainly children from rural areas who are supposed to be less supervised, spending most of time outdoor, thus being more exposed to serious injuries. The case severity is also due to the relatively long

distance to a specialized medical service (9, 10, 11).

The variations during the study interval showed a minimum in 2012 and a maximum of cases in 2016, in line with national statistical reports, but also from Galați County. The continuous increases in the number of motor vehicles and driving license holders result in an increase in the number of road traffic accidents with polytrauma, deaths and disabilities (12).

Studies conducted in Europe and North America highlighted the fact that starting with May, the number of polytrauma cases increases, reaching a peak in autumn during October-November (13, 14). As a result, ED services are highly demanded during this period. If the victims are children, the timing of road accidents with polytrauma evidenced some peculiarities. Starting with May, there is an increase in outdoor activity during summer holidays. The children rashness and imprudence (6-14 years), unsupervised preschool children (3-6 years), but also excessive speed of drivers is the main causes of polytrauma (15, 16). Our study highlighted a significant difference in the number of children with polytrauma during summer months as compared with other seasons. As also reported in the literature (17), the distribution of polytrauma in our study showed a peak at the end of the week.

A multicentric study (18) conducted by the *Pan-African Pediatric Surgery Association* (PAPSA) was carried out for 31 days (May 1 - June 1, 2015) on pediatric trauma admissions, simultaneously, in 15 surgical centers, from 11 countries (3 high income, 5 middle income, 3 low income). The study revealed that there were 1,377 pediatric admissions for trauma, of which 1,295 in 10 centers in low-income countries and 84 in 5 centers in high-income countries. Children were 7 years old, of whom 62% were males. Road traffic accidents were the most frequently involved (41%), followed by falls (41%) and violence (11%).

In a study (19) conducted in 2009-2010 in ED Tîrgu-Mureș, Romania, one of four trauma patients was found to be due to a road accident, and of the 718 patients treated for trauma due to road accidents, most of them were young adults aged 18-29 (30.5%), and male gender represented more than two-thirds of patients (66.9%). Children aged 0-17 accounted for 33.3% of all injuries caused to pedestrians. Most injuries happened on national roads (71.4%), and rural roads were involved in 2.9% of cases.

Our study has certain limitations. The collected data may be representative for Galati County, but not for the entire country. Data was collected in a limited interval of time. It is possible to be cases that have been lost from the record. However, the results of our study might help ED management for pediatric cases admitted with polytrauma, and further research will complete the existing data.

CONCLUSIONS

Our study may be a starting point for establishing a medical and prevention strategy for polytrauma at pediatric age. Age of 8-10, male gender and rural area were more frequently demographic characteristics of study group. Road traffic accidents occurred in summer during the weekend was the most frequent pattern involved in pediatric polytrauma. These results may facilitate the ED management to be more adapted to pediatric patients, allowing a faster orientation of medical staff and resources. On the basis of the data obtained in our study, primary prevention measures regarding polytrauma may also be initiated.

DIAGNOSTIC DILEMMAS IN PANCREATIC ADENOSQUAMOUS CARCINOMA - CASE REPORT (Abstract): Adenosquamous carcinoma of the head of the pancreas (ASCAP) is a very rare tumor (1-2%), consisting of both squamous cell carcinoma (required 30%) and ductal adenocarcinoma. ASCAP is a malignant tumor with debatable histogenesis. We report the case of a 54-year-old man, with a history of more than half of a year of right upper quadrant abdominal pain, jaundice, with no anamnestic data of acute or chronic pancreatitis, or substance abuse. On gross examination the tumor was solid, white, poorly circumscribed, located in the head of the pancreas, with 4 cm diameter, and direct extension into ampulla of Vater, common bile duct, and peripancreatic soft tissue. Microscopically, the tumor was composed of squamous polygonal cells arranged in small glandular structures, with tightly packed pattern, and mild nuclear pleomorphism, along with small areas with Alcian blue positive intracellular mucin. Therefore, the differential diagnosis between ASCAP and pancreatic collision tumor, metastasis of adenosquamous carcinoma or mucoepidermoid tumor was compulsory. The immuno-histochemistry assay confirmed ASCAP as the final diagnosis, based on the intense positive reaction for cytokeratin 7 mainly in the glandular structures, whereas cytokeratin 5 and p63 were positive predominantly in the squamous component. The present report aimed to highlight the pathological characteristics of this rare subtype of pancreatic tumors and to point out the difficulty in differentiation between a pancreatic and an extra pancreatic (biliary tract or ampulla of Vater) tumor, due to the extensive tumor growth that interests, in advanced stages, the same anatomical space, given the different prognosis and therapeutic approach of these entities. **Keywords**: ADENOSQUAMOUS CARCINOMA, PANCREATIC TUMOR, COLLISION TUMOR.

Adenosquamous carcinoma of the pancreas is a malignant tumor consisting of both squamous cell carcinoma and ductal adenocarcinoma components (1). These entities can vary in amount and distribution, a 30% squamous differentiation being

required according to some authors for a positive diagnosis (2). It represents a rare entity, being described in 1-2% cases of exocrine pancreatic tumors (3). This paper presents a case and reviews the characteristics of a rare pancreatic malignancy.

CASE REPORT

We are presenting the case of a 57-year-old patient, with no medical history of acute or chronic pancreatitis, hospitalized in the "Sf. Spiridon" County Clinical Emergency Hospital from Iasi with jaundice and acute calculous cholecystitis. He was admitted in the emergency room with right upper quadrant abdominal pain for about 2 weeks. The patient did not mention any relevant personal or familial medical history aside from an appendectomy. Physical examination outlined sclero-tegumentary jaundice and hyperchromic urines.

Laboratory tests at admission showed high WBC (10,360/µL) associated with elevated transaminases (ALT = 522 U/L, AST = 267 U/L), as well as other liver disease markers (GGT = 760 U/L, ALP = 556 U/L). The hepatic pathology was sustained by the critical levels of bilirubin, with a maximum of 21.86 mg/dL and the conjugated bilirubin of 9.27 mg/dL at admission starting to normalize and maintaining levels between 2 and 3 mg/dL.

The abdominopelvic CT revealed a nodular mass in the head of the pancreas (33/31/32 mm), well demarcated, hypodense, with anfractuous areas inside, being in close proximity to the superior mesenteric vein. Two lymph nodes of 7 mm and 6 mm, respectively, were discovered in the retroduodenopancreatic space as well as the atrophy of the neck, body and tail of the pancreas, and the dilatation of the pancreatic duct. The common hepatic duct and the intrahepatic bile ducts were dilated in both lobes and gallbladder hydrops was present. The right kidney had a cortical cyst of 16 mm and the prostate showed hypertrophy (34/49/46 mm). A solid retroperitoneal nodule (15/12/19 mm) was also detected in the left iliac fossa, adjoined to the psoas and iliac muscles. The exam concluded the diagnosis of a neoplasm located in the head of the pancreas cT2N1M1 with retroperitoneal metastasis.

The surgery included both duodenopancreatectomy and cholecystectomy, which revealed normal features of the gallbladder and a tumor in the pancreatic area. The gross specimen consisted of gastric tissue (3 cm), duodenal tissue (12 cm) and pancreatic tissue (5.5/4.5/3.5cm). A histopathological examination identified a large tumor located in the head of the pancreas (4.2/3.3/3.2 cm), showing firm consistency, white color, and being poorly demarcated, with direct extension into ampulla of Vater, common bile duct, and peripancreatic soft tissue (fig. 1).

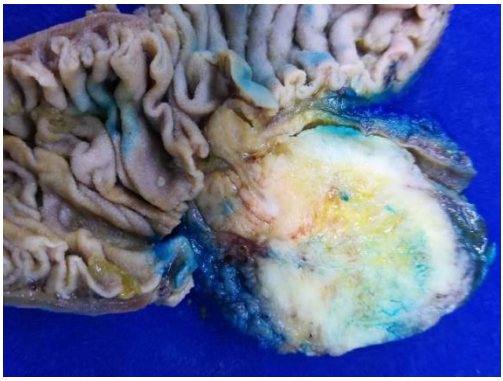

Fig. 1. White, poorly demarcated pancreatic tumor, with direct extension into common bile duct

Multiple sections were stained with hematoxylin and eosin (H&E) and Alcian blue (AB). Microscopic examination of the

pancreatic tumor in H&E showed an adenosquamous carcinoma with biphasic malignant growth, identified as squamous cells with keratohyalin granules and glandular structures with mild nuclear pleomorphism associated with small areas with AB positive intracellular mucin (figs. 2-5).

Perineural invasion, luminal necrosis, desmoplastic stroma, and necrotic areas were also identified. Pancreatic tumor showed diffuse invasion into the thickness of the biliary duct, without duodenal wall involvement. Peripancreatic lymph nodes were not dissected. Furthermore, the gallbladder revealed signs of chronic cholecystitis and the remainder of the pancreatic tissue was modified (atrophied acini, hyperplasia of the neuroendocrine islets, interstitial fibrosis, and mild chronic inflammation), suggesting chronic pancreatitis. Immunohistochemical staining was performed to demonstrate pancreatic biphasic tumor. Therefore, immunolabeling for cytokeratin 7 was positive mainly in the glandular structures, whereas cytokeratin 5 and p63 were positive predominantly in the squamous component (figs. 6-8).

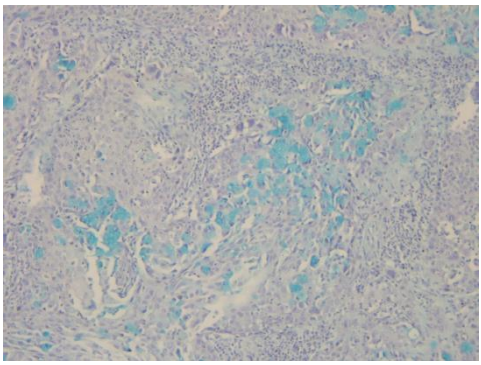

Fig. 3. The adenocarcinoma component of the tumor with glandular structures containing intracellular mucin (Alcian Blue positive staining)

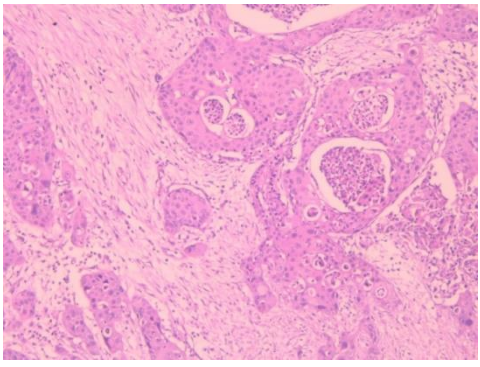

Fig. 4. Squamous differentiation with infiltrative nests of polygonal cell, intercellular bridges, eosinophilic cytoplasm, and variable degrees of keratinization

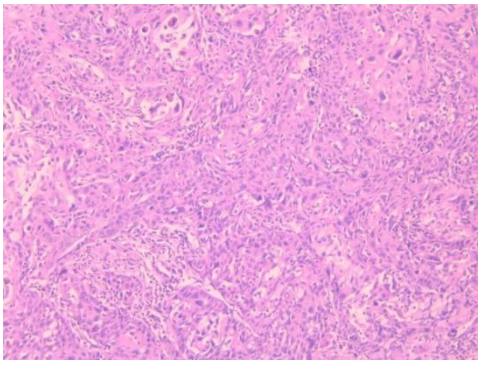

Fig. 5. Two different patterns intimately admixed with the tumor

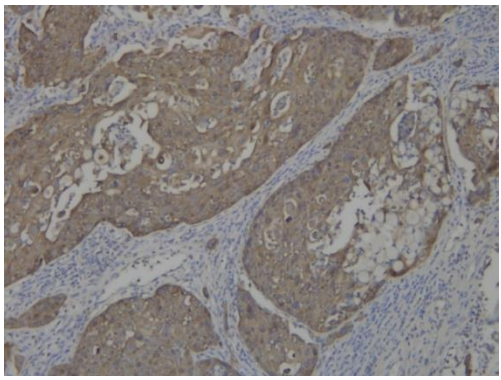

Fig. 6. Tumor cells positivity for cytokeratin 5 predominantly in the squamous cells and in few adenocarcinoma components

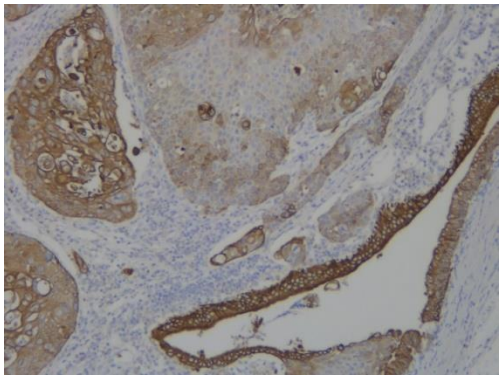

Fig. 7. Immunoreactivity for CK 7 restricted to the glandular component, while the squamous component is mainly negative

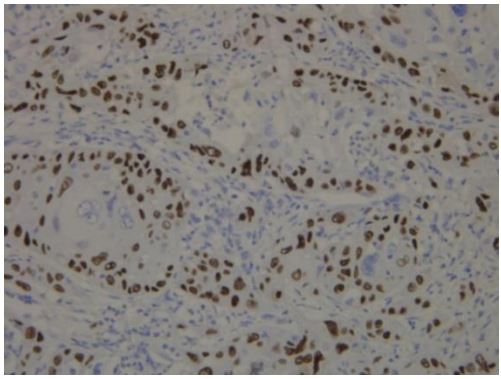

Fig. 8. Immunoreactivity for p63 is restricted to the squamous component, while the glandular component is negative

The patient had a difficult and complicated postoperative course, during which he also developed ascites and fluid in the right pleural cavity. The examination of the liquid showed an infection with *Enterobacter cloacae*, *Pseudomonas aeruginosa*, and *Candida spp*.

The wound was re-examined after two weeks and the results came back positive for *Klebsiella pneumoniae*. The patient was discharged 50 days after admission, when the infection was completely resolved.

DISCUSSION

The first known case of adenosquamous carcinoma was reported in 1907, when Herxheimer referred to this lesion as "cancroide" (4). Adenosquamous carcinoma is a rare entity on its own, making it an even more interesting case with the occurrence in the pancreatic tissue. The reported cases were seen more commonly in organs such as lungs, esophagus, colon, stomach or salivary glands (3). WHO 2010 classification synthesizes pancreatic cancers as ductal adenosquamous carcinoma, neuroendocrine neoplasms, cystic tumors, solid pseudopapillary tumors, acinar cell carcinoma, adenocarcinoma, squamous cell carcinoma, primary lymphoma, and metastatic lesions (2). A study published in 2012 by Boyd *et al*. (5) reviewed 415 patients with this kind of tumor and concluded that it is most commonly located in the head of the pancreas with 185 cases (44.6%), while the body/tail tumors appeared in 121 cases (29.2%). Males are slightly more affected than females (54.5% *vs.* 45.5%) with the mean age of incidence of 66 years and a racial distribution with Caucasian dominance (about 80% of patients) (5).

Adenosquamous carcinoma of the pan-

creas (ASCAP) has an even more aggressive tumor behavior than the ductal adenocarcinoma (DADC), with a median survival of less than one year (2), and its body or tail locations have a rare occurrence (3, 5).

The histogenesis of ASCAP remains uncertain, raising controversies regarding its origin, with several theoretical hypotheses launched nowadays. One of them proposes a preexisting adenocarcinoma undergoing squamous cell transformation, while another supports its origin from a heterotopic squamous epithelium transforming into a malignant entity. It is also possible that a stem cell population could be able of differentiation into either a squamous or glandular pattern, followed by malignant transformation (6, 7). However, the clinical and macroscopic aspects are general and very similar to other pathologies, including abdominal pain, weight loss, anorexia, and jaundice, making it difficult to diagnose (3, 8). CT imaging may show more conclusive aspects, including large infiltrative lesions and the presence of central necrosis. Nabae *et al*. (9) concluded that the presence of these features in a large pancreatic tumor seems to be suggestive of the diagnosis of adenosquamous carcinoma of the pancreas (9). Serum data and radiology examination are not very helpful, as this type of tumor has no differentiating aspects from the DADC (10).

Currently there are no guidelines for treating patients with ASCAP due to its rarity and diagnosis difficulties. Treatments are similar to those for adenocarcinoma and are mainly based on local resection, with three main surgical methods performed to ensure a long-lasting survival: pylorus preserving pancreaticoduodenectomy (PPPD), distal pancreatectomy (DP), and total pancreatectomy (TP) (7).

Adjuvant radiotherapy and chemotherapy does not play an important role in the prognosis of ASCAP. Literature highlights that the median survival period of patients treated with radiotherapy/chemotherapy is increased (13 months/7 months) compared to patients that have not received radiotherapy/chemotherapy (6 months/5 months) (10).

The prognosis of this type of cancer is poor, with a median survival range of 4.6 to 9 months. Nevertheless, the outcome after pancreatic resection shows improvement (5.2-10.8 months), with a survival rate of 33.4% after 1 year and 17.2% after 2 years *vs.* 25.5% and 14.0% in patients that had no pancreaticoduodenectomy (PD) (7).

The main diagnosis issue of ASCAP is derived from the difficulty in differentiation from a biliary tract or ampulla of Vater tumor, due to similar morphology and the extensive tumor growth that interests the same anatomical space. The differential diagnosis also took into consideration a pancreatic collision tumor, metastasis of an adenosquamous carcinoma or mucoepidermoid tumor from other organs. It is crucial to differentiate between this particular histological type from other malignancies, in order to evaluate the diagnosis consequences for the management of the patient.

CONCLUSIONS

Adenosquamous carcinoma of the pancreas remains a rare and complicated diagnosis to manage, with important difficulties in patients' treatment. From the clinical examination to the laboratory and imaging tests, it is crucial to differentiate between this particular histological type and other malignancies, such as adenocarcinoma,

being aware of the diagnosis consequences for the treatment options. With a poor prognosis even after resection of the tumor, more studies need to be conducted in order to fully understand the implications and the outcome of this disease.

NEWS

FLUOROQUINOLONE USE AND RISK OF AORTIC ANEURYSM AND DISSECTION

The objective of this study was to investigate whether oral fluoroquinolone use is associated with an increased risk of aortic aneurysm or dissection. This is a retrospective study conducted using linked register data on patient characteristics, filled prescriptions, and cases of aortic aneurysm or dissection. Results: within the 60-day risk period, the rate of aortic aneurysm or dissection was 1.2 cases per 1000 person years among fluoroquinolone users and 0.7 cases per 1000 person years among amoxicillin users (amoxicillin is an antibiotic with no known association with aortic aneurysm or dissection). Fluoroquinolone use was associated with an increased risk of aortic aneurysm or dissection (hazard ratio 1.66 (95% confidence interval 1.12 to 2.46)), with an estimated absolute difference of 82 (95% confidence interval 15 to 181) cases of aortic aneurysm or dissection by 60 days per 1 million treatment episodes. In a secondary analysis, the hazard ratio for the association with fluoroquinolone use was 1.90 (1.22 to 2.96) for aortic aneurysm and 0.93 (0.38 to 2.29) for aortic dissection. Conclusions: in a propensity score matched cohort, fluoroquinolone use was associated with an increased risk of aortic aneurysm or dissection. This association appeared to be largely driven by aortic aneurysm. (Pasternac B *et al*. *BMJ* 2018; 360: 678).

THE IMPORTANCE OF THE NEUTROPHIL TO LYMPHOCYTE RATIO AS A PREDICTIVE FACTOR FOR THE OCCURRENCE OF INTESTINAL NECROSIS IN PATIENTS WITH INCISIONAL HERNIAS

THE IMPORTANCE OF THE NEUTROPHIL TO LYMPHOCYTE RATIO AS A PREDICTIVE FACTOR FOR THE OCCURRENCE OF INTESTINAL NECROSIS IN PATIENTS WITH INCISIONAL HERNIAS (Abstract): The **aim** of the present study was to establish the importance as a predictive factor of the NLR (neutrophil to lymphocyte ratio) for the occurrence of intestinal necrosis in patients with incisional hernias. **Material and methods**: We conducted a retrospective study including 141 patients over a 3-year period in which we analyzed the values of NLR. **Results**: Thus, we noticed that there is a direct, statistically significant correlation between the NLR and the indication of small bowel resection in patients with incisional hernias. Depending on the binary variable resection yes or no, we set a cutoff threshold of 2.553 with predictive value, threshold for which we have the best values of sensitivity and specificity as performance parameters. Over this threshold the sensitivity increases, so the patients or the risk of resection is highly appreciated, AUC=0.853 (CI 95%=0.784 to 0.907), p<0.001. **Conclusions**: Increased NLR values may play a particularly important role in predicting the existence of intestinal necrosis in patients with incisional hernias. NLR values above 2,553 are commonly associated with the appearance of necrosis or ischemia in the small intestine in these patients. **Keywords**: INCISIONAL HERNIAS, NEUTROPHIL TO LYMPHOCYTE RATIO.

Incisional hernias are a common condition in patients with a history of abdominal surgery. Their incidence varies depending on the type of surgery performed, as well as the associated comorbidities of the patient, which varies between 9 and 20% (1).

The occurrence of incisional hernias in the vast majority of cases is frequently associated with the onset of abdominal pain syndrome, with the presence of intestinal transit disorders, these aspects usually requiring surgical treatment, sometimes even in emergency (2). Some of the main complications that can occur in patients with incisional hernias are strangulation, respectively incarceration or irreducibility

of bowel. The appearance of these post operatory complications can endanger the life of these patients and impose the emergency surgical treatment of these cases, mainly due to the risk of intestinal necrosis or of the peritonitis (3, 4).

In the last years, more and more emphasis has been placed on the specialty literature on the importance of systemic inflammatory syndrome as a prognostic factor in the pathogenesis of neoplastic or non-neoplastic disorders. Most commonly, the extent of the systemic inflammatory syndrome is quantified by calculating the ratio of serum neutrophils (NEU) value and serum lymphocytes (LYM) value (5, 6). The purpose of the present study was to establish the importance as a predictive factor of the value of the NLR ratio for the occurrence of intestinal necrosis in patients with incisional hernia, as well as to establish a cutoff value of the NLR with a predictive value in these cases.

MATERIAL AND METHODS

In order to achieve the proposed purpose, we conducted a retrospective observational study over a 3-year period between 01.01.2016 - 31.12.2018 in which we included 141 patients who were admitted to the Surgery Department of Onesti Municipal Hospital. As exclusion criteria from the study it should be mentioned that, we excluded from the study patients who at the time of admission had clinical signs of other inflammatory conditions. We also excluded patients with incarcerated incisional hernia who required resection of the large intestine.

In all the patients studied, at the time of routine hospitalization, routine blood tests were collected (complete blood count (CBC), serum biochemistry, coagulation). In the case of CBC, we were mainly interested in the serum level of the NEU, LYM, serum monocytes (MON), serum platelets (PLT) and serum white blood cells (WBC). Based on these, the value of the NLR levels was calculated in all patients.

RESULTS

From the descriptive analysis of the processed data we obtained a relatively uniform distribution over time for the cases registered in the statistics of the surgical department (tab. I). From the analysis of the age of the studied patients we observed that they were between 19 and 89 years old.

TABLE I

Distribution by year

YEAR				
		Frequency	Percent	Valid Percent
Valid	2016	46	32.6	32.6
	2017	39	27.7	27.7
	2018	56	39.7	39.7
	Total	141	100.0	100.0

Regarding the distribution by sex of the patients we noticed that, in the studied group 31 patients were male (22% of cases) and 110 patients were female (78% of cases). In all the patients studied, the timing of the surgery was decided according to the general medical condition of the patients and the local clinical examination of incisional hernias. Thus, in the case of patients presenting with clinical signs of

bowel obstruction or local clinical signs of incarcerated incisional hernia, it was decided that the surgery should be performed urgently. In this sense it can be observed that in 46 cases it was decided that the surgery should be performed urgently and in 95 cases the surgery was scheduled (tab. II).

TABLE II

The time of the surgery

EMERGENCY / SCHEDULED SURGERY				
		Frequency	Percent	Valid Percent
Valid	E	46	32.6	32.6
	S	95	67.4	67.4
	Total	141	100.0	100.0

At the time of surgery in 27 cases (19.1%) intraoperatively the trophic disorders (necrosis or ischemia) was found in the ring of the peritoneal diverticula, which determined the need for bowel resection (tab. III).

TABLE III

Incidence of intestinal resection

SMALL BOWEL RESECTION YES / NO				
		Frequency	Percent	Valid Percent
Valid	YES	27	19.1	19.1
	NO	114	80.9	80.9
	Total	141	100.0	100.0

From the descriptive analysis of the values of the serum hemogram in the studied patients we observed that the value of the serum hemoglobin (Hb) and the serum hematocrit (Ht) have a Gaussian distribution, this fact allowing their expression by means and standard deviation (SD). On the other hand, the value of NEU, LYM, MON, WBC, PLT and NLR respectively, did not have a Gaussian distribution, this fact determining their expression by median, minimum and maximum. In terms of NLR levels they ranged from 0.7055 to 18.4160 (tab. IV).

TABLE IV

Descriptive analysis of the distribution of serum hemogram and NLR values

	Age	HG	HTC	NEU	LYM	MON	PLT	WBC	NLR
Mean	64.55	13.6318	40.9064	5156.31	2012.62	507.59	249035.46	7903.97	3.041186
Median	67.00	13.6000	40.4000	4340.00	1910.00	440.00	239000.00	7000.00	2.270900
Std. Deviation	12.131	1.51099	4.16793	2812.367	824.489	268.323	88485.545	3097.283	2.5581158
Minimum	19	9.80	30.20	1630	480	100	56000	2600	.7055
Maximum	89	17.00	49.90	20210	6810	2290	797000	23900	18.4160

In the case of the multivariate statistical analysis of the correlation between the NLR value and the indication of intestinal resection in the studied patients we applied the Mann-Whitney test, which compares the difference between the medians. Thus,

we observed the existence of a direct, statistically significant correlation between the value of NLR and the indication of bowel resection in these patients ($p<0.0001$) (fig. 1).

Next, in the case of the subgroup with bowel resection (27 patients) we tried to establish the existence of a correlation between the value of the neutrophil to lymphocyte ratio and the hemogram parameters. In this regard, we applied Spearman - type correlations between all quantitative variables. Thus, we observed that in these patients the NLR value correlates with the level of leukocytes, neutrophils, lymphocytes and serum monocytes, but not with the level of serum platelets. The results are presented in table V (**: Correlation is significant at the 0.01 level - 2-tailed, *: Correlation is significant at the 0.05 level - 2-tailed).

Forwards, through statistical analysis, we tried to establish the cutoff value of the NLR which correlates with the necessity of practicing intestinal resection in patients with incisional hernias. Depending on the binary variable resection yes or no, we set a cutoff threshold of 2.553 with predictive value, threshold for which we have the best values of sensitivity and specificity as performance parameters. Over this threshold the sensitivity increases, so the patients or the risk of resection is highly appreciated, AUC=0,853 (CI 95%=0.784 to 0.907), p < 0.001, Sensitivity 85.20%, Specificity 72.80%. The values are represented in figure 2.

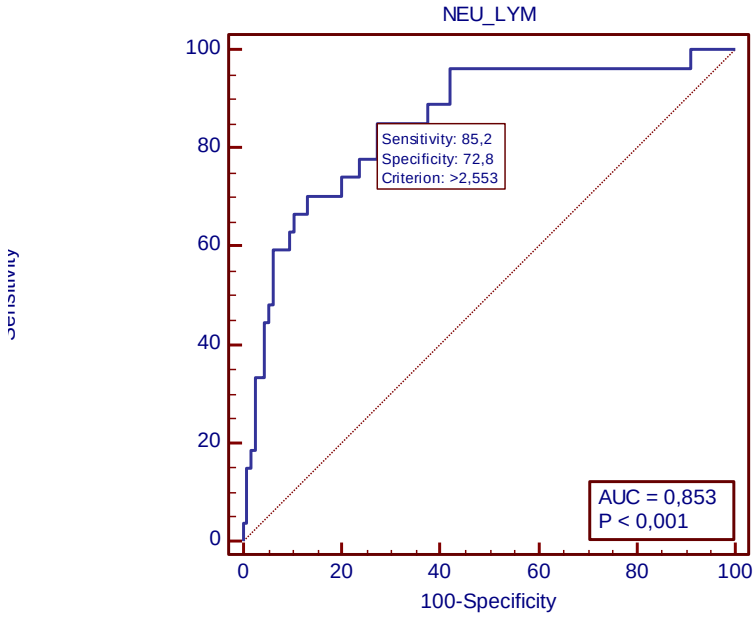

Fig. 2. Establishing the cutoff value of NLR that correlates with the indication of intestinal resection

DISCUSSION

In the vast majority of cases the appearance of a local complication in patients with incisional hernias (incarceration, strangulation) determines the appearance of a local inflammation which is frequently followed by the onset of a systemic inflammatory syndrome. Usually the factor that triggers systemic inflammatory syndrome is the activation of NEU (11). NEU activation occurs in most of the cases following their migration to the inflammatory outbreak. On the other hand, it is recognized at present that LYM play an inhibitory role in the migration of inflammatory cells as well as neoplastic cells. It has also been shown that increased LYM levels are a marker of immune system activation (12, 13).

The increase of the NLR value in the vast majority of cases denotes the increase of the serum level of the NEU accompanied by a relative decrease of LYM. Few studies in the literature have investigated so

far, the importance as a prognostic factor of NLR in patients with incisional hernias (14-16). In addition to the local inflammation that exists in patients with incisional hernias, another factor that may explain the increase of NLR in patients with intestinal necrosis is the existence of mesenteric ischemia, a fact also demonstrated by other authors in the literature (17-19).

Several studies have shown that the value of NLR correlates with the severity and prognosis of inflammatory syndrome in different conditions (20, 21). The major advantage of determining the value of NLR in patients with incisional hernias is that it does not require special tests, it is only necessary to perform blood hemograms, blood tests that are not expensive and are performed routinely in all patients admitted in different hospital units.

In our study we observed that the NLR median in patients who required bowel resection was 4.566 and in the case of patients who did not require bowel resection the NLR median was 2.045. Also, by statistical analysis we established the cutoff value of NLR that is predictive for the necessity of practicing an intestinal resection of 2.553 (sensitivity 85.20% and specificity 72.80%). In a study published in 2016 by Zhou in patients with incarcerated groin hernias, it was observed that the NLR median value that required intestinal resection was 6.5 (18, 22).

The present study has certain limitations due to the fact that it is a retrospective study, also being performed on a relatively small number of patients. Also, some clinical parameters (hemodynamic status, respiratory status of patients admitted to hospital) were not included in the study. Thus, further prospective, randomized studies are needed to establish the cutoff value of NLR that correlates with the risk of developing small bowel necrosis in patients with incisional hernias in much larger cohorts of patients.

CONCLUSIONS

Increased NLR values may play a particularly important role in predicting the existence of intestinal necrosis in patients with incisional hernias. NLR values above 2.553 are commonly associated with the appearance of necrosis or ischemia in the small intestine in these patients.

A SHORT HISTORY OF THE HISTOLOGICAL PROCESSING TECHNIQUES FOR TOOTH AND SUPPORTING HARD TISSUES (Abstract): Knowledge of the microscopic morphological tooth structure is compulsory for dental practice and research. The paper aims to present some major milestones in the evolution of hard tissue processing techniques, used in the histology laboratories for the analysis of the different specific tissues belonging to the tooth and supporting hard tissues. Decalcification is a mandatory step for processing these tissues. The decalcified tissues are subsequently impregnated with a suitable substance such as paraffin or celloidin. Despite the technical advances in medicine, the histopathological methods of tooth and supporting tissues processing are still difficult. The decalcification procedure can be replaced by non-decalcifying techniques. Technical problems are amplified by the fact that teeth and periodontal structures are extremely difficult to sample in humans under normal conditions. **Keywords**: TOOTH, DECALCIFICATION, EMBEDDING, PARAFFIN, CELLOIDIN.

Knowledge of the microscopic morphological tooth structure is compulsory for competent dental practice (1). Almost all dental specialties start from histology. The following examples are eloquent in this respect: cariology is directly related to the histoarchitecture of enamel and dentine, endodontics is related to the connective assembly specific to the dental pulp, periodontics and implantology are based on the morphological individuality of the periodontium, pedodontics shows the tooth germ developing elements, orthodontics integrates movements and forces inside the tooth attached to the periodontium.

On the other hand, research in the field of dentistry requires a good comprehension of tooth histology, whether it involves fundamental or clinical studies (1). However, the histological processing techniques for teeth and supporting hard tissues are difficult, due to the main characteristic of their structure, namely the hardness gained as a result of the mineralization process. Enamel is the hardest tissue in the body, with a degree of mineralization of 98-99%, followed by dentin, with a degree of mineralization of 70%, alveolar bone, with a degree of mineralization of 55% and cementum, with 45% mineralization (2, 3).

With strict reference to the deep periodontium, technical problems are doubled by structural peculiarities, the alveolar bone being part of the maxillary bone and, consequently, impossible to separate and taken from the human being, in normal conditions (3). This is confirmed by the fact that numerous periodontal studies are performed on experimental models, in animal species (4-7). Therefore, the periodontal research in humans is focused primarily on implants, following the elements of biocompatibility and bio integration that "mimic" a restoration of the components of the deep periodontium, close to the histoarchitecture resulting from the embryonic development and, subsequently, the eruption processes of the deciduous and permanent dentition. Other research directions target various bone grafting techniques and materials, such as bone augmentation and acceleration of recovery through the addition of natural or synthetic growth factors (8).

Within this context, our aim is to present some major milestones in the evolution of hard tissue processing techniques, used in the histology laboratories for the analysis of the different specific tissues belonging to the tooth and supporting hard tissues.

Decalcification is a mandatory step for processing these tissues.

One of the first solution for hard tissue decalcification was already known since 1882 – namely Perenyi's fluid composed by 10% nitric acid 40 mL, 0.5% chromic acid 30 mL, and absolute alcohol 30 mL (9). It is worth to mention that Perenyi's fluid is also used at the moment (10, 11). However, the first tooth processing techniques that include decalcification and paraffin/ celloidin embedding were reported starting with the 2nd decade of the 20th century (9, 12-14). A wide range of decalcification methods have been proposed, some of them having currently only a historical value (9, 12-15).

The removal of inorganic component (namely the calcium ions) from the hard tissue can be done with the help of strong mineral acids, weak organic acids or chelating agents (10, 11, 16, 17). The common strong mineral acids are hydrochloric acid (5-10% in distilled water) and nitric acid (5% in distilled water). A "classic" variant for this type of decalcifying solution is von Ebner's fluid, based on hydrochloric acid, saturated sodium chloride and distilled water (9, 13). All these reagents ensure a rapid decalcification, but the reaction time must be carefully monitored because the staining will be altered when the end-point is exceeded (10, 17). The class of weak organic acids class includes formic acid (10% in distilled water), trichloroacetic acid and picric acid (17). The third method relies on chelating agents that ensure the elimination of calcium ions from the hydroxyapatite crystals and, subsequently, diminishing their size. The main reagent is the ethylenediaminetetraacetic acid (EDTA). The major inconvenience of this method, the long processing time, is counteracted by significant advantages which derives from the fact that hard tissues preserve their organic structure (10, 17). For that reason, the usage of chelating agents is highly recommended for morphological and molecular studies (10, 17).

Table I summarizes some examples for old decalcification methods (9, 12-15).

The decalcified tissue is subsequently impregnated with a suitable substance such as paraffin or celloidin. The impregnation process is named embedding (11-16).

TABLE I

Historical aspects in decalcification

DECALCIFYING SOLUTION	WORKING TIMES, FEATURES
Schulz, 1922: saturated solution of chlorine dioxide (yellow gas, toxic) in acetic acid with trade name "Diafanol"	- washing - immersion in ethyl alcohol 70° - immersion in solution - dehydration - paraffin/celloidin embedding
Drahn, 1926: extemporaneous preparation, consisting of 10 parts saturated aqueous solution of chlorine dioxide (made in appropriately equipped chemistry laboratories), and one part concentrated sulfuric or nitric acid	- technique made in specially designed niches, or in sealed containers - immersion in solution - dehydration - paraffin/celloidin embedding
Gooding and Stewart 1932: solution composed of formic acid 5-25 mL, 40% formaldehyde 5 mL, distilled water 75 mL).	- immersion in solution - dehydration - paraffin/celloidin embedding
Murray, 1937: solution 1, consisting of equal parts absolute ethyl alcohol, chloroform and acetic acid; solution 2, consisting of equal parts of chloral hydrate and phenol, mixture melted at 60°C and then kept fluid	- immersion in solution 1 for 12 hrs. - immersion in solution 2 up to 1-6 days - dehydration - paraffin/celloidin embedding
Greep, 1948: 5% formic acid pure or in combination with 10% formalin, OR 2% formic acid and 20% sodium citrate in equal parts	- immersion in solution for 2-10 days - wash in tap water for 24 hrs. - dehydration - paraffin/celloidin embedding
Evans and Krajian, 1930: formic acid 25 mL, sodium citrate 10 g, distilled water 75mL	- immersion in formic acid buffered with citrate - dehydration - paraffin/celloidin embedding
Kristensen, 1948: formic acid 18 mL, sodium formate 3.5 g, distilled water 82 mL	- immersion in formic acid buffered with sodium formate - dehydration - paraffin/celloidin embedding
Clayden, 1952: 5% fuming nitric acid solution (7.5 cc fuming nitric acid (d 1.40) and distilled water up to 100 cc)	- immersion in fuming nitric acid 5% - immersion in 0.1% urea aqueous solution, with stabiliz ing role, or 0.1% formalin, to prevent collagen swelling - immersion in 5% sodium sulphate for 24 hrs. - wash in tap water for 24 hrs. - dehydration - paraffin/celloidin embedding
Freiman, 1954: EDTA in phosphate buffer with pH 7.4, associated with 10% formalin	- immersion in solution for 4-5 days - rinse in tap water or ethyl alcohol 70° - dehydration - paraffin/celloidin embedding
Lorch, 1964: solution: 14.7 g crystallized citric acid; 0.2 N 700 mL sodium chloride solution, 0.1 N 300 mL hydrochloric acid solution; 1% zinc sulphate solution 2 mL; chloroform 0.1 mL	- fixation in ethyl alcohol or cold acetone (0-4°C)for 24 hrs. - decalcifying in the Lorch mixture for 3-10 days - wash in tap water for 24 hrs. * indicated for histochemical methods
Lillie, 1965: 5% sulfuric acid solution	- does not require further treatment with sodium sulphate, but only a flush with running water for 24 hrs - dehydration - paraffin/celloidin embedding
Lillie, 1965: 15% ammonium citrate, pH 7-8	- the fluid is changed several times, for 6 days - dehydration - paraffin/celloidin embedding * indicated for histochemical methods

Both paraffin and celloidin impregnation follow the same standard stages: dehydration, sample immersion in specific solvent, sample immersion in paraffin/celloidin at higher concentrations, block casting and solidification (11-16).

The common procedure of dehydration, by using alcohols in ascending concentrations, is not suitable because paraffin and celloidin are not soluble in alcohol. Therefore, other solvents were advised based on their properties to dilute the embedding medium, namely xylol or oil of cedarwood for paraffin, and mixture of equal parts of ether and alcohol, or equal parts of absolute ethylic alcohol for celloidin (11-16). The length of time which is necessary for solvents to penetrate the specimens may range between 12-24 hours, depending upon size and permeability of the tissue (enamel, dentin, cementum, alveolar bone) (11-16).

The usage of paraffin for the hard tissue had several disadvantages, the more important being the fragility of the decalcified specimens due to the heating imposed by the method. Therefore, celloidin embedding has been strongly recommended because it produces less shrinkage, despite the prolonged working time (11-16).

Celloidin for histological use is a solid or soluble mixture of mono- and dinitrocellulosis. The solid form looks like flexible translucent plates, dry or imbued in alcohol.

The soluble form has a variable concentration (2-4-8%), is viscous like honey and is delivered already dissolved, resulting in a consistent elastic mass (11-16). Celloidin is highly inflammable, so all handling stages should take place in well ventilated areas, avoiding any contact with fire sources (11-16).

Data presented in Table II are interesting, as they reveal different olden versions of celloidin impregnation.

TABLE II

Historical aspects in celloidin embedding

METHODS	FEATURES
Apathy Method, 1912 (18)	
- dehydration in absolute ethyl alcohol (3 baths for 4 hrs.) - immersion in the mixture of absolute ethyl alcohol and anhydrous ethyl ether, in equal parts (4 baths for 6-12 hrs.) - immersion in 2-4% celloidin solution (2-4 days) OR 8% celloidin solution (1-2 weeks) - casting and hardening of the celloidin block	- for dehydration, small crystallizers or weighing capsules are used, both provided with a hermetic lid; they must be kept in an anhydrous atmosphere, in a sulfuric acid dryer or under a glass bell under which an anhydrous calcium chloride has been placed in a vessel - the volume of the 2-4% celloidin solution should exceed the specimens by 0.5-1 cm - for casting the blocks baths of 8% celloidin solution are used; it is necessary that, by a slow evaporation, the volume of the baths is reduced by 50%, the concentration of the celloidin solution thus reaching 16% - the definitive completion of the block requires 70° ethyl alcohol which is poured into a thin layer in the inclusion vessels of the crystallizer and covered with a tight lid for several hours for the appearance on the surface of the inclusion baths of a well-solidified celloidin crust, 70° ethyl alcohol is further added to the celloidin in the baths, which by the loss of absolute alcohol will solidify into a compact block in 24 hours, which will be extracted from the container, using a scalpel * The celloidin hardening can be done, under the same conditions, with chloroform or with a mixture of 70° ethyl alcohol and glycerin in a ratio of 2:1 - the blocks of celloidin are preserved in 70° ethyl alcohol

METHODS	FEATURES
Seki Method, 1937 (19)	
- dehydration with absolute methyl alcohol - immersion in celloidin solution with increasing concentrations: 2% (for 24 hrs.), 4% (for 2 days), 8% (for 4 days) - casting of the blocks: treating the celluloid bath with a squirt of vapor water until the solid crust is formed, then adding a solution of 70° ethyl alcohol ten parts and three parts chloroform which will be change 1-2 times.	- the use of methyl alcohol ensures a better penetration of the parts and consequently the shortening of the working time - the blocks solidify in 1-6 days, and are stored in 70° ethyl alcohol - sections smaller than 15 microns are difficult to obtain
Wolf Method, 1940 (20)	
- rinse in tap water - immersion in three regular glycerin baths (24 hrs.) - immersion in three baths of anhydrous glycerin (specific weight 1.26) (6-12 hrs.) - immersion in celloidin solution with 8% concentration - casting of the blocks	- it is recommended to use tall containers to ensure the su pension of the pieces at the top of the solution. - the duration of inclusion by this method is shorter.

The last decades of the 20th century brought important changes in the working methods specific to histopathology (21, 22), due to the technical advances in medicine.

The effectiveness of decalcification was improved by several approaches, including ion-exchange resins added to decalcifying solutions (23), electrolytic decalcification (24), sonication applied with chelating agents (25) or microwave processing (26-28). A number of papers showed that, compared to classical methods, microwave ensures a shorter decalcification time; despite this fact, the heat can damage the tissue morphology and can lead to defects in tissue staining (22, 27, 28).

Nevertheless, hard tissue processing – mostly tooth processing is still difficult, and the technologies available today for tooth and supportive tissue processing are extremely expensive – which is why the number of specialized laboratories for this approach is limited.

Reviewing the evolution of the histopathological working methods in hard dental tissues, we consider the non-decalcifying technique to be of interest. Three examples for these techniques are relevant. The first example refers to the Exakt system (Exakt, Hamburg-Norderstedt, Germany) designed and developed in the 80' (29, 30) allows the histological study of jaws with teeth and/or implants of metallic or ceramic materials (2-5) and, consequently, permits the analysis of the tooth and supporting hard tissue. According to the working protocol applied by the Hard Tissue Research Laboratory at the University of Minnesota School of Dentistry (31), the specimens are fixed in buffered neutral 10% formalin (the fixator volume being 10 times higher than the sample volume) minimum 24-48 hours. Afterwards, the tissue fragments are dehydrated, then impregnated and embedded in a type of synthetic resin, which is subsequently cut with special devices, capable of penetrating hard tissues (i.e. Exact band-cutting system based on a diamond or carborundum-coated cutting band). Vestibular-oral and mesio-distal sections, or cross-sections, can be performed. However, the section thicknesses are much larger (35-50 µm) compared to those obtained by de-

calcification processes (3-5 μm). The dehydration and impregnation process takes about one month. The specimens are colored with different stains (including fluorochrome labelling and fluorescence examination), which can differentiate between different degrees of bone maturity and between vital, non-vital, calcified and non-calcified elements. Computer-assisted image analysis is frequently used, leading to the accumulation of histomorphometry information, which can objectively assess the percentage of vital bone, non-vital graft bone, or non-bone materials (for example, various types of hydroxyapatite). Fluorochrome-labelled bone fluorescence microphotography is also common. In the analysis of the implant-tissue interface, the evaluation of the osseointegration of the bone with the metallic surface is possible. The most difficult is to collect the samples ensuring the presence of an area of alveolar bone, without damaging the maxillary structure. The second example refers to cryomicrotomy, technique based on the immersion of non-decalcified tooth in liquid nitrogen and subsequent sectioning with a cryostat using a heavy-duty freezing microtome (32, 33). By cryomicrotomy, the cellular and extracellular structures of hard tissues are well conserved and can be analyzed in light and electron microscopy, and also investigated by using immunohistochemistry. The third example consists in a petrographic technique, firstly applied in 1974 (34), for the histological processing of teeth (35). This method used dried teeth embedded in a resin (Epo-Tech 301 resin). The teeth were grounded down to half using 600 grit carborundum, thinned using a diamond bladed rock saw, grounded down to 40 μm thickness using 600 grit carborundum and then polished using 3 grades of diamond paste. Finally, the tooth specimen of 30 μm thick were analyzed in fluorescence microscopy in order to assess the tetracycline presence, as indicator for the tooth growth (35). Despite the complexity of the procedure, the obtained results sustain the method's potential to bring new data regarding the tooth hard tissues.

FINAL REMARKS

The histopathological methods of tooth and supporting tissue processing are difficult. The decalcification procedure can be replaced by non-decalcifying techniques. Technical problems are amplified by the fact that teeth and periodontal structures are extremely difficult to sample in humans under normal conditions.

HEMOLYSIS - AT THE BORDER OF THE CONTROVERSY OR MALPRACTICE (Abstract)**:** Clinical laboratory medicine provides nowadays significant level of reliability of adequate measurement and testing, as well as a quality assurance in hemostasis assays through modern analyzers. However, many non-conforming samples are still recorded and reported due to events which are not always under the control of the laboratories. Numerous studies indicate that most sources of error in hemostasis laboratories occur with the blood collection procedure for prothrombin time (PT) and activated partial thromboplastin time (APTT) determination. The purpose of this study is to provide a better understanding upon the potential interference between hemolysis and in vitro coagulation mechanism. **Materials**: In order to create a comprehensive approach to the effect of hemolysis on hemostasis determinations, we performed a search in the main databases which included original studies reviewed by specialists in this field. **Results:** For the clinical laboratory, hemolysis is the most frequent error of the samples, accounting for 54-65% of all non-compliant samples. We have referred to studies in which hemolysis was mechanically provoked, studies that were based only on macroscopic identification, and last but not least, on studies in which plasma hemoglobin concentration was determined. **Conclusions:** This study could represent the premise for revising the policy of refusing the hemolyzed samples as a result of the controversial outcomes that are not considered clinically relevant. **Keywords**: hemolyzed plasma, rejection, prothrombin time, activated partial thromboplastin time.

The evaluation of hemostatic system function in clinical laboratories is based on screening tests: prothrombin time (PT) measuring the extrinsic pathway and activated partial thromboplastin time (APTT) that corresponds to the intrinsic pathway (1). In 2000, Carraro and colleagues pointed out that out of the total number of nonconformities, 60% of the rejected specimens were hemolyzed (2). Hence, concerning transmittance of the results it is suggested that clinicians should be aware about this, in order to exclude an *in vivo* hemolysis (2). In 2006, US pathologists recommended additional investigations for samples with hemolyzed plasma, for identifying possible *in vivo* hemolysis (3).In the same year, Lippi and colleagues concluded that in the case of *in vivo* hemolysis, *in vitro* hemolysis is difficile to be avoided (4).

During *in vivo* hemolysis, the process of red blood cells destruction triggers the release of hemoglobin (5-7), the process being either physiological or pathological, whenever is exceeding certain levels. The etiology of hemolytic syndromes is various

and represents a common cause of anemia syndromes (5-7). Clinically it manifests by icteric skin, while laboratory tests point toward evidence of anemia of various degrees, namely normochromic, normocytic, hyperbilirubinemia with predominance of the indirect bilirubin, increased LDH (lactate dehydrogenase) activity, reticulocytosis, and decrease of haptoglobin (5-7).

Congenital and acquired hemolytic anemias can be associated with thrombotic phenomena. Several studies revealed thus that particular autoimmune hemolytic anemia with warm antibodies are associated with thrombotic manifestations, with 15-33% of these patients experiencing venous thromboembolic events (8). Hence, there is a need for tests to investigate hemostasis which can accurately acknowledge this thromboembolic risk, in order to help the clinician in establishing appropriate treatment. One of the general conditions to be considered in a laboratory performing coagulation tests is related to the quality of the collected biological product. The plasma should not be hemolyzed or with fibrin, and the sample should not contain clots (9-11).

Hemolysis is one of the error sources in the pre-analytical phase, and could interfere with the manner of tests assessment in the analytical phase (12-14). Coagulation tests determination in hemolyzed plasma samples generates the activation of platelets (14) and *in vitro* coagulation (15), hence preventing clot detection through optical techniques, as a response to the reaction(1, 13, 16). The activation mechanism is not clearly understood, so that speculations are made based on the membrane phospholipids release as a result of erythrocyte lysis, which in turn could generate a shortening of the coagulation time (17). Because of these variables, the results of the coagulation tests determinations will reflect the accuracy of the pooled sample, and will not precisely reflect the clinical condition of the investigated patient (13). The consequences may sometimes be particularly serious for the patient (9) and equally for the health system in general (18), as these determinations are frequently considered as “diagnostic” (13). The incidence of hemolyzed plasma samples is a common phenomenon in clinical laboratories and is a reason for their rejection (9, 19, 20) due to the interference with the determinations. It is difficult to decide which of the recommendations is more effective as most studies argue based only on the results obtained on small group of patients, a larger study being therefore recommended (1).

The aim of our study is to shed some light on the effect of hemolysis upon the *in vitro* coagulation mechanism. The main objective is thus identification of the recommendations resulting from the literature based on the paraclinical studies, in order to adopt the appropriate conduct in relation to performing hemostasis determinations, from the hemolyzed samples.

MATERIALS AND METHODS

The progress of the current literature review was performed using the PubMed, Google Scholar and Cochrane database records, based on the following keywords: pre-analytical, post-analytical, hemostasis, hemolysis, incidence, hemoglobin, *in vivo*, *in vitro*, results, shortened, PT, APTT, rejected, controversy, investigations, malpractice, comments, information, diagram, visual, clinician, clot. In order to understand the *in vitro* mechanism, we scanned for more recent, peer-reviewed original studies describing the effect of the *in vitro* hemolysis on PT coagulation and APTT coagulation determinations. Study protocols, reported cases as well as opinion polls have been considered.

It was not necessary to obtain informed consent, as the research was based on the cases and protocols presented by colleagues in the literature, which describe the incidence and effect of hemolysis in the context of coagulation determinations.

RESULTS

This review has some limitations given the small number of papers that were referred. Despite this fact, the selected articles can be considered reliable as they describe the samples and the methods used according to the scientific criteria. Being accepted for publication, the selected studies shed some light upon the understanding of the effect of *in vitro* hemolysis on the determination of PT and APTT coagulation tests. After the initial review, the data were abstracted using a table and have summarized: the interpretation of hemolysis, as well as the mechanism of induction of *in vitro* hemolysis used by some authors, as described in the first table.

DISCUSSION

The incidence of hemolyzed plasma is common in medical laboratories performing coagulation tests, being a reason for refusing the determinations based on these samples (1, 13, 16). During our research, we found studies in which the authors triggered the *in vitro* hemolysis by aspirating 1 ml of blood from the primary sample, followed by strong expulsion in the tube through a 23 G needle (9). The experiment was repeated by Hernaningsih and Akualing who used 3ml of blood aspirated in a syringe, creating thus hemolysis by expulsion. This operation was performed twice or thrice (1). The results obtained from non-hemolyzed samples compared to those acquired after induction of the *in vitro* hemolysis from the same sample (9) were included as reference data. We also referred to studies involving macroscopically identified hemolysis specimens (17), as well as those in which the *in vitro* hemoglobin concentration has been measured (2). In their study, Woolley *et al.* obtained hemolyzed plasma by adding cells that were mechanically hemolyzed (20).

Carraro *et al.* highlighted the importance of clinicians' awareness upon such aspects (2). Their results recorded the following: 5 out of 16 cases confirmed by *in vivo* hemolysis would not have been suspected by clinicians, in the absence of the essential laboratory contribution which flagged these critical situations, contributing thus to a significant improvement of the medical decisions (2). Moreover, by performing an observational study to identify the possible shortened PT tests as a result of the interference of the *in vitro* tissue factor (FIII) with the determination, during 4 months we recorded 544 tests with results below the minimum normal range (10"-14") [21]. Furthermore, upon repeating the PT determination from the same sample, 200 tests were corrected, falling within the normal range (21). Of the remaining 344 shortened tests, 27 tests (21) were correlated with the elevated values of bilirubin (22), suggesting thus a potential *in vivo* hemolysis, in agreement with Carraro's and collaborators research (2). In their study, Bonini *et al.* stated that more than 60% of all laboratory errors come from the pre-analytical phase (23). Guder mentioned that the diagnosis accuracy is given by the performance of the analyses in the field of medical laboratories (24), recalling the 60's and 70's when the quality assurance of the analytical procedures was introduced, as well as the extra-analytical variables which influence the precision of the laboratory results (25). In order to avoid hemolysis caused by environmental factors during transport, starting with the 70'sthe glass tubes for biological sampling have been replaced with capped specimens (24). Although the measurement of plasma hemoglobin concentration is practiced in some laboratories, it is often macroscopically

assessed by laboratory specialists (9,17), by coloring the plasma or serum from pink to red (26).

In some studies, a color chart was used to assess plasma hemolysis such as that provided by Arora *et al.*, Plumhoff *et al.*, and Zhao *et al.* (9, 27, 28). The numbers indicate the extent of hemolysis expressed in mg/dl (20, 28-30). Hemolysis is visible at a serum hemoglobin concentration of 0,2-0,3 g/l (17, 20, 31). Laga and colleagues measured the value of the supernatant hemoglobin in the specimens included in the study, reporting hemolysis at values above 30 mg/dl, assuming there was no hemolysis at ranges such as 20 mg/dl (17). The interval between 20-30 mg/dl was left to the appreciation of the person interpreting the hemolysis (17). The results obtained by Hernaningsih and Akualing (1) were consistent with the studies performed by Laga (17) and Arora *et al.* (9), clarifying the clinically insignificant influence of the *in vitro* hemolysis on the PT test if the patient's results are within the normal reference range (1). They claimed that one cannot refer to these conclusions for patients with lower or upper limit of this range, as they could have clinically significant implications (1). In the case of the APTT test, in order to validate quantitatively the hemolysis interference, the authors referred to the existing research in which differences that could not be explained were found between the results obtained from hemolyzed and non-hemolyzed plasma samples (1).

In the research performed by Hernaningsih and Akualing in subjects with initial test results within the normal reference range, a shortening of the APTT test from the hemolyzed plasma samples have been recorded (1). The results agreed with the study by Lippi *et al.* (4). In 2006, Laga *et al.* correlated the prolongation of APTT in healthy volunteers, and shortened APTT in study group patients with low levels of FVIIa (proconvertin) (17). As the mechanism of shortening the test in the hemolyzed samples was not constant, it was correlated with the possible release of intracellular substances from leukocytes, of phospholipids from erythrocytes or with platelet-induced activation of coagulation (16,32). Among the literature data, we identified a study by Favaloro *et al.* that describes the decrease of PT and fibrinogen level following the activation of the coagulation cascade (13). The APTT prolongation or shortening test is influenced by the fibrinogen loss or fibrinogen activation (13). Two years later, Arora *et al.* agreed with Laga's study and used photo-optical instruments to determine APTT from hemolysed samples for healthy volunteers, recording prolongation of the test (9,17). Hernaningsih and Akualing did not investigate the effect of hemolysis on PT and APTT prolongation in patients that were administered oral anticoagulant therapy (1), although previous studies suggested that the PT test in hemolyzed samples could be determined through electromechanical or optical instruments (17,33) From the clinician's point of view, the accuracy of the coagulation tests results is of critical importance, the promptness of the diagnosis and the appropriate treatment depending on it.

Thus, if the hematologist picks up the results of the APTT coagulation tests in such cases, without any awareness from the laboratory, he is entitled to regard the results as to be real and continues the investigations in order to provide a proper diagnosis. For a prolonged APTT, the following will be considered: the presence of a LA (*Lupus Anticoagulant*) or a genetic or acquired coagulation factor deficiency. If the

latter is advised, then the investigations will assume in the first stage the plasma composite test, followed by evaluation of the activity of coagulation factors and inhibitors that modulate APTT: factor VIII (anti-hemophilic A), factor IX (anti-hemophilic B), antibodies anti-factor VIII, and anti-factor IX. If APTT is shortened, the investigations will continue to identify the pathological conditions associated with an increased thrombotic risk, knowing that a shortened APTT reveals an increased thromboembolic risk (34). In both situations, we are discussing about complex investigations with a considerable financial impact on the hospital budget, which adds to the patient's discomfort facing the unnecessary investigations.

The laboratory should inform the clinician upon the possibility of coagulation investigation tests interference with hemolysis, because the orientation may be different: it may draw the attention of the physician to complete the investigations for a proper diagnosis of hemolytic anemia (reticulocytes, total and direct bilirubin, lactate dehydrogenase, haptoglobin, peripheral blood smear), especially in case of a mild anemic syndrome without clinically significant changes. Due to the fact that studies have pointed that hemolytic anemia is associated with increased thromboembolic risk, in case of the presence of hemolysis secondary to an *in vivo* hemolysis and shortened APTT, the therapeutic response will be marked by anticoagulant therapy to prevent the occurrence of thrombotic incidents (35). In this situation cut down APTT is intended to alert the physician regarding this risk. In order to study the effect of hemolysis on PT and APTT tests, cell lysis was mechanically obtained, this being similar to factors inducing *in vitro* hemolysis (1, 9, 36). The prolongation or shortening of PT and APTT tests also depends on tissue factor release due to mechanical cell lysis (1).

Starting with 2015, we also pay special attention to the incidence of hemolyzed plasma samples (37), intending an approach that could turn this in patient's favor. Although previous studies recommend rejecting these samples, in our laboratory, we determine PT and APTT tests from hemolyzed samples and the results are accompanied by a textual explanation, being in agreement with Carraro and collaborators, attracting the attention of hemolysis possible interference: ***"Sample with hemolyzed plasma, possible interference with the determination"***. Favaloro *et al.* recommend for these samples verification by different methods, to exclude the accidental presence of the clot in the erythrocyte sediment (13). Starting with 2014, we implemented a re-verification and post-analytical procedure based on transvasation, which allows us to highlight the clot (38).

In the case of an intensely hemolyzed plasma, we inform the clinician about this aspect, recommending resampling and textually explaining the non-compliance: "Repeat the sampling. Highly hemolyzed plasma sample". This behavior is in accordance with the recommendations in the national specialized literature, where it is mentioned that the rejection of a hemolyzed plasma sample without obligatory information from the clinician can be a proof of malpractice (39,40). As long as the result is not accompanied by information that assists the clinician in the correct interpretation of the results, it is quite a challenge for the medical practitioner to issue proper decisions (40). In a very recent study, differentiating *in vitro* from *in vivo* hemolysis is even imposed for laboratory

specialists, motivated by the fact that the sample is admitted in the laboratory without seeing the patient (41). Referring to previous studies, Wan Azman *et al.* consider the rejection of these samples to be inappropriate, and in order to perform proper differentiation they recommend blood smear examination (41), also supporting the addition of a brief comment suggestive for the reluctance in the interpretation of the results (41-43). As a necessity, the authors pay attention to the need for a laboratory guide to focus on standardizing how to interpret hemolyzed samples, so that essential information to be provided to the clinicians for further proper management of the patients (41). Wan Azman *et al.* urge upon the bidirectional communication between laboratory specialists and clinicians, as being of paramount importance in seeking solutions based on each patient condition (41).

To reduce pre-analytical errors, the development of quality indicators (QI) can serve as tool for pre-analytical activities control and monitoring (44). In agreement with Magnette's study, by educating the medical personnel involved in the biological product sampling process, we can help reduce, understand and raise awareness of the effects of pre-analytical variables on the coherence and reliability of coagulation screening tests (45,46).

CONCLUSIONS

Considering all the mentioned aspects, a link between the medical laboratory and clinicians should be issued, in order to exclude any *in vivo* hemolysis that could be disregarded as a result of the rejection of samples with hemolyzed plasma. Performing routine screening tests from specimens with a certain degree of hemolysis is accepted, and clinicians may receive reports about the outcomes that fall within the normal reference range. For patients which follow anticoagulant therapy, the results should be reported with caution, and the possible interference of hemolysis with the determination need to be explained. The policy of rejecting hemolyzed specimens should be reconsidered, as duplicated sampling creates patient's discomfort, delayed decision making in critical situations, and last but not least, can trigger additional costs for the hospitals' budget and the health sector in general.

Further research on a large scale samples would be requisite, further testing in order to study the coagulation factors which fall under the influence of *in vitro* hemolysis that is directly reflected in the quantification of PT and APTT tests, being recommended.

ABBREVIATIONS

PT - prothrombin time

APTT - activated partial thromboplastin time

LDH - lactate dehydrogenase

FIII - tissue factor

FVIIa - proconvertine

LA - Lupus Anticoagulant

factor VIII - anti-hemophilic A

factor IX - anti-hemophilic B

QI - quality indicators

ACKNOWLEDGMENTS

Thanks to the Hematology Department team from ,,St. Spiridon" Hospital, Iasi, Romania for supporting the comments implementation regarding clinicians' information of the hemolysis interference with coagulation tests determinations.

BREAST CANCER IN MALE (Abstract) : The aim of this study is to point out the late diagnosis and initiation of treatment in male with breast cancer. At the same time, to show the importance of the correlation between different markers in assessing the prognostic, as well as the treatment for the patient. **Material and methods** : Retrospective study on a group of 15 males with breast cancer, out of 1043 patients with the disease, in a period of 10 years. Eight patients were stage III of disease, 2 were stage II, one was stage I, and in other 3 cases the evaluation of the tumor and of the axillary lymph nodes was performed only by echography, considered stage II. **Results** : All patients underwent radically modified Madden mastectomy ; 4 patients needed a partial resection of the great pectoralis muscle. Adjuvant chemotherapy was performed in 9 patients, and neoadjuvant chemotherapy in 2 cases. Three patients refused the chemotherapy, and one patient chose an alternative paramedical treatment. The treatment with Tamoxifen was done in 11 patients with high values of Progesterone and Estrogen Receptors (PR, ER). At the date of our study, 8 patients were alive, without clinical signs of disease (free of disease), while in 3 patients, alive, clinical signs of disease were detected (recurrence). Survival rate couldn't be evaluated in 4 patients. **Conclusions** : Breast cancer in male is usually discovered in locally advanced stages, although most of the patients are regularly screened for chronic hepatitis. Use of biological markers allows a more accurate evaluation of the aggressiveness of the tumor, as well as a more specific treatment for each patient. Modified radical mastectomy type Madden remains the preferred surgical approach. Surgical approach should be considered even in locally advanced cases, as well as in elder patients. **Key words** : BREAST CANCER IN MALE, BIOLOGICAL MARKERS, MADDEN MASTECTOMY

THE PREVALENCE OF *HELICOBACTER PYLORI* INFECTION IN A HOSPITAL FROM NORTH-EAST OF ROMANIA

THE PREVALENCE OF *HELICOBACTER PYLORI* INFECTION IN A HOSPITAL FROM NORTH-EAST OF ROMANIA (Abstract). This study aims to analyze the prevalence of *Helicobacter pylori* infection in a hospital from North-East of Romania. **Material and methods**: *H. pylori* infection was investigated in 2,048 patients at Emergency County Hospital Bacău. *H. pylori* infection was diagnosed by fecal antigen test. The patients were analyzed based on demographic criteria, and by presenting pathology. **Results**: Out of 2,048 patients tested in one year, 819 patients (39.9%) were positive for *H. pylori*. No statistically significant differences were identified between men and women (40.3% *vs.* 39.8%, p=0.821). Patients from rural areas had a significantly higher prevalence of *H. pylori* infection than urban areas (47.3% *vs.* 36.8%, p=0.00001). A direct correlation was noted between *H. pylori* infection and age. There was a significantly higher average age in patients with *H. pylori* infection (*H. pylori* (+): 51.1±22.3 *vs. H. pylori* (-): 49.1±21.3, p=0.0323). The highest prevalence was in patients aged 31-40 years (54.3%) and the lowest in patients aged 0-6 years (25.8%). Regarding the wards where patients were admitted to, the highest prevalence was on the Internal Diseases ward (50.71%), while on the Gastroenterology ward the prevalence of *H. pylori* infection was not significantly different from other sections with less cases of digestive pathologies (Gastroenterology 41.2%, Endocrinology 42.9%, Nephrology 48.6%). **Conclusion**: The prevalence of *H. pylori* infection in people who presented at the Emergency County Hospital Bacău is lower than the figure estimated for Romania in a recent meta-analysis (2017) performed globally. **Keywords**: H. PYLORI , PREVALENCE, FECAL ANTIGEN TEST.

Helicobacter pylori (*H. pylori*) infection is one of the most widespread infections worldwide, being a real public health issue (1). About 30-80% of world's population is infected with *H. pylori*, the prevalence varying from one country to another depending on economic status. General data shows that prevalence of *H. pylori* infection differs in developing countries (approximately 70%) from developed countries (approximately 34.7%) (1, 2).

These prevalence differences are also influenced by socio-economic status, degree of urbanization, and access to running

water and medical services of those countries. Even across the same country the prevalence of *H. pylori* infection can vary (2, 3). For developing countries, including Romania, prevalence of *H. pylori* infection in middle-aged adults is approximately 80%. Although no national study has been completed, a recent meta-analysis estimates a prevalence of *H pylori* infection in Romania of 65.6%-71.5% (1, 4).

Considering different age groups, the literature (1, 2) shows a lower prevalence in children (less than 20%). A systematic review by Ibrahim et al (4) of the data from 244 studies revealed male gender is more commonly associated with *H. pylori* infection in both children (OR=1.06, 95% Cl: 1.01 - 1.12, I^2 (total heterogeneity / total variability)=43.7%) and adults (OR=1.12, 95% Cl: 1.09 - 1.15, I^2=68.5%).

The present study analyses the prevalence of *H. pylori* infection in the population who presented at Emergency County Hospital Bacău. Thus, the presence of *H. pylori* infection was investigated in 2048 patients tested between 1st June 2018 and 31st May 2019.

The presence of *H. pylori* was tested using fecal antigen test, a non-invasive method with 90% specificity and 88-89% sensitivity (5, 6).

The method can be used both to detect infection and to control its eradication. Factors that may influence its sensitivity are diarrhea (in loose stool, the fecal antigen for *H. pylori* is diluted), use of antibiotics and proton pump inhibitors (5). Also, in patients with upper gastrointestinal bleeding there is a low sensitivity of fecal antigen test for *H. pylori* . Other factors that may influence the diagnosis are temperature and the time interval between harvest and analysis. Stool samples should be stored at low temperatures and tested soon after collection. To prolong antigenicity, stool samples must be stored at -80°C (6).

MATERIALS AND METHODS

This study includes 2,048 patients aged 0-90 years, from both rural and urban areas, who presented at Emergency County Hospital Bacău between 1st June 2018 and 31st May 2019. All patients were tested for *H. pylori* using fecal antigen test. Patients were grouped and analyzed based on demographic criteria (age, gender, environment: urban/rural areas), as well as on the ward where they had been hospitalized.

Statistical analysis

The categorical variables were presented by number and proportions and compared with the *Chi-square* test. Kolmogorov-Smirnov test was used to assess whether the continuous data shows a normal distribution. Continuous variables (normally distributed) were expressed by mean ± standard deviation (SD) and compared using the ANOVA test. The general prevalence of *H. pylori* infection was calculated as follows: (all individuals with a positive *H. pylori* test) / (all individuals who underwent *H. pylori* testing). A stratified analysis of *H. pylori* prevalence was performed by age groups on genders and by background (urban/rural). The Joinpoint regression model was applied to evaluate the correlation between age and prevalence with *H. pylori*. The junction points where prevalence of *H. pylori* assessed for all age groups began to increase or decrease were identified. For this, we constructed the univariable regression of a connection point in which relationships between age and *H. pylori* prevalence were analyzed. The annual percentage change (year of age) (APC) was calculated with the corresponding 95% confidence interval (CI) for each effect estimate.

Finally, a logistic regression analysis (univariate / multivariate) was created to assess the relationship between *H. pylori* infection, gender, and patient background. The odd ratio (OR) was calculated with 95% CI. *p*-values lower than 0.05 were considered statistically significant. The statistical analysis was performed using the trend analysis software *Joinpoint Regression Program version 4.8.0.1*, 2020 (National Institutes of Health, Maryland, United States) and *SPSS version 24.*

Ethical approval

The present study was approved by the Ethical Committee of Emergency County Hospital Bacău. All patients provided informed consent for inclusion in the present study (parents or legal guardians signed the informed consent for children). For all data obtained, personal identifying information was in accordance with the laws of privacy protection in Romania and hospital regulations.

RESULTS

During the analyzed period, out of 2,048 patients tested, 819 were positive for *Helicobacter pylori* (fig. 1).

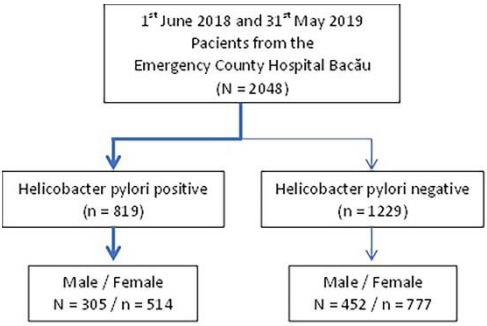

Fig. 1. Flow chart of patients included in the study

The overall prevalence of *H. pylori* infection was 39.9%. The presence *of H. pylori* did not show a significant association (p=0.8217) with gender (male / female: 40.3% / 39.8%). Patients with *H. pylori* infection had a significantly higher mean age (p = 0.03239) (51.1±22.3) compared to those who tested negative (49.1±21.3). The prevalence of *H. pylori* was significantly (p=0.00001) increased in patients from rural areas (47.3% *vs.* 36.8%) (tab. I).

TABLE I

Demographic characteristics of the analyzed patients

	All groups	*Helicobacter pylori*		Statistic test	p-value
		Yes (n=819)	No (n=1229)		
		39.9%	60.01%		
Age (years old) mean ± SD		51.1±22.3	49.1±21.3	4.124 †	0.03239*

Environment (U/R), n (%)	1442/626 (69.43/30.57)	523/296 (36.8/47.3)	899/330 (63.2/52.7)	19.82294 §	0.00001*

§ Pearson Chi-square test; † ANOVA test; (*) Marked effects are significant at p<0.05

Analyzing the prevalence of *H. pylori* infection by age groups, it was showed that in children under 18 the prevalence was 38.6% (114/295). Thus, between 0-6 years the prevalence was 25.8% (23/89), between 7-13 years 45.9% (45/98), and between 14-18 years it was 42.6% (46/108). The highest prevalence was noted in the 31-40 age group with 54.3% (89/164) (tab. II, fig. 2).

TABLE II

***H. pylori* infection prevalence based on age and gender**

Age (years)	Total cases (n=2048)			Total cases with *H. pylori* (n=819)		
	All	male	female	*H. pylori* total	male	female
0-6 years	**89**	38	51	**23**	8	15
7-13 years	**98**	56	42	**45**	21	24

Totals	**2048**	**757**	**1291**	**819**	**305**	**514**

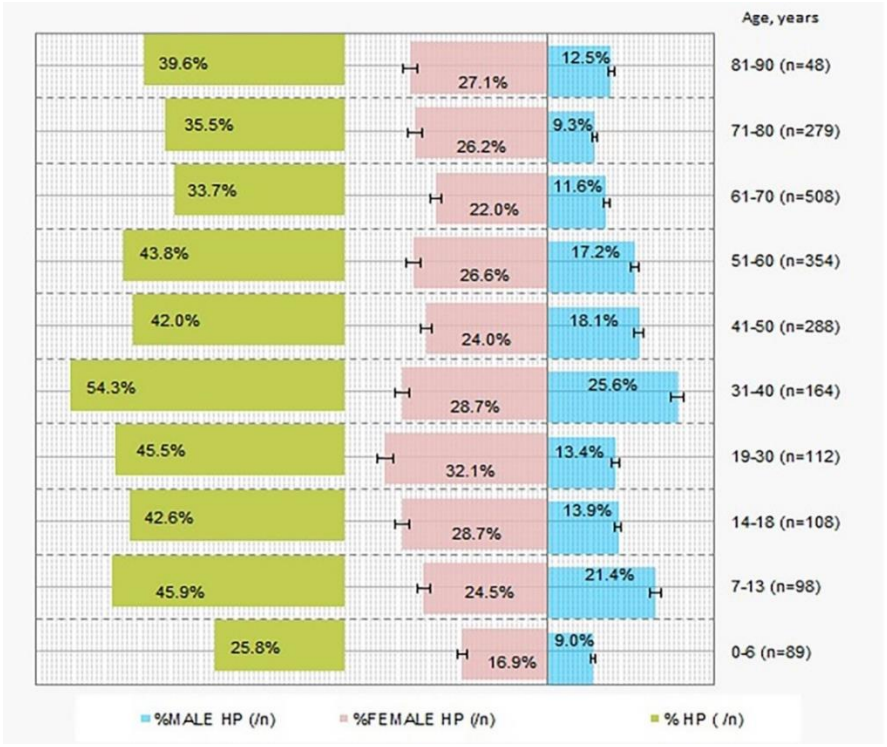

Fig. 2. *H. pylori* infection prevalence according to age and gender

Both univariate and multivariate analysis indicated that age and rural origin are the predictive factors for presence of *H. pylori* infection. Therefore, for age, an OR value of 1.48 was calculated (95%CI: 1.276–2.387, p<0.0001). For patients from rural areas, the risk of *H. pylori* infection was 2.84 times higher compared to that of patients from urban areas (OR=2.849; 95%CI: 2.186 – 3.713, p <0.0001) (tab. III).

TABLE III

Univariate and multivariate logistic regression analysis used for identifying predictive factors for *H. pylori* infection

***H. pylori* infection**	**Univariate logistic regression**				**Multivariate logistic regression**			
	Odd ratio	95% confidence interval		p-value	Odd ratio	95% confidence interval		p-value
		Lower	Upper			Lower	Upper	
Age	1.996	1.292	2.687	0.043*	1.481	1.276	2.387	<0.0001*
Male	1.020	.849	1.225	0.832	1.007	.835	1.214	0.943
Rural	1.542	1.275	1.865	<0.0001*	2.849	2.186	3.713	<0.0001*

(*) Marked effects are significant at p<0.05

Based on *Joinpoint* regression model, a nonlinear association was observed between patients' ages and prevalence of *H. pylori* infection (fig. 3). In patients younger than 7 years (33 cases) there was a significant association between increased age (≤7 years) and high prevalence of *H. pylori* (APC=21.34%; 95%CI: 5.8 – 39.2, p=0.0062), reaching a peak at age 7, with an observed gross rate of 47.1% (modelled gross rate: 48.3%). In patients aged 7-28 years, prevalence of *H. pylori* infection did not change significantly with age but presented a slightly decreasing trend as age progressed (APC= -1.28%; 95%CI: -3.4 – -0.8, p = 0.2528) (tab. IV, fig. 3).

The regression analysis for the next age group, 28-31 years showed an increasing, although insignificant, prevalence trend. This indicated an APC of 12.85% (95%CI: 2.8 - 21.8, p=0.7671) which suggests an insignificant positive linear regression of prevalence in the 28-31 years age group (tab. IV, fig. 3).

TABLE IV

APC - annual percentage change for the regression slopes of patients ages and *H. pylori* infection prevalence

	Age(years)		**APC**	**APC**		**Test Statistic (t)**	**p-value**
	Lower Endpoint	**Upper Endpoint**		**Lower CI**	**Upper CI**		
Slope 1	1	7	**21.34**	5.8	39.2	2.813585	0.006291*
Slope 2	7	28	**-1.28**	-3.4	0.9	-1.152507	0.252873

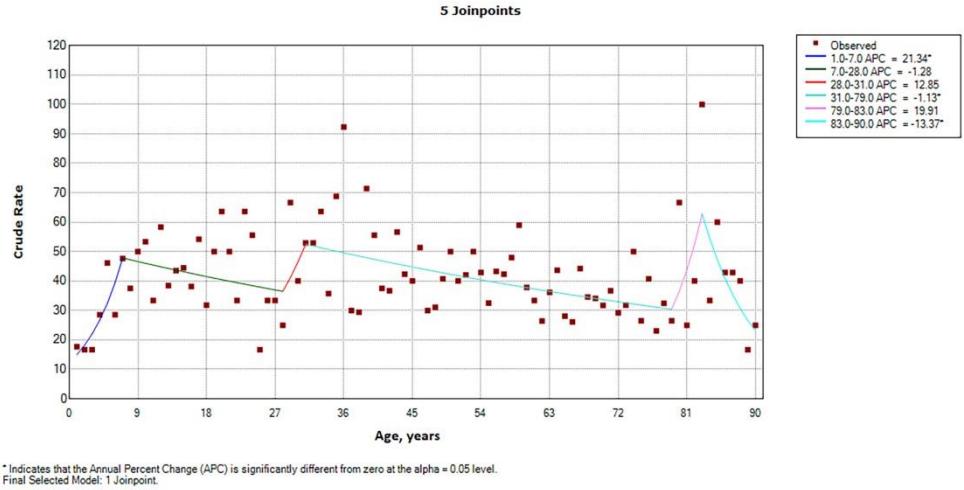

Fig. 3. Correlation between patients' age and *H. pylori* infection prevalence

In the age group 31-79 years, the prevalence of positive *H. pylori* cases showed a significant negative linear regression. Thus, in this age interval, the increase in age brought about a decrease in positive cases (APC= -1.13, 95%CI: -1.7 – -0.5, p=0.0004). The gross rate observed at 79 years was 31.4%, and gross modelled rate was 29.9%. For the 79-81 age group there was a marked increase in prevalence, but it is insignificant (p=0.3749). However, a significant decrease in prevalence with age was observed for the 83-90 years group which registered an increased APC value of -13.37 (95%CI: -22.3 – -3.5, p=0.01). This result clearly indicates a significant decrease in positive cases for the 81-90 age group (Table IV, Fig. 3). Overall, the gross prevalence of *H. pylori* infection did not show significant differences between women and men (p=0.8217). Out of 2,048 patients included in the study, 967 patients were admitted to various wards for different pathologies. The request for *H. pylori* testing was made by gastroenterologists, or by doctors who considered it necessary to test for *H. pylori* infection in patients with extradigestive disorders. For these patients, the prevalence of *H. pylori* infection was 43%. Thus, there is a significant association (p <0.0001) of *H. pylori* infection in patients with nephrological pathology (48.6%), endocrinological pathology (42.9%), diabetes or nutritional diseases (37.9%). Less cases were identified in patients with dermatological or allergic conditions (28.6%).

DISCUSSION

The present study regarding the *H. pylori* infection in patients at Emergency County Hospital Bacău, shows a prevalence of 39.9% of infection. This prevalence is considerably lower than the national estimate from a meta-analysis done in 2017 (65.6-71.5) (1). However, the value falls within the prevalence interval of other Central or East-European countries (1, 7). One explanation would be that testing in our study was done in the general population, without differentiating between previously treated (experienced) and naive pa-

tients. The large number of patients tested (2048) made such a specification difficult. The result obtained (39.9%) may entail that some of these patients had undergone an effective treatment to eradicate *H. pylori* infection, as showed by a negative fecal antigen test.

Considering the different age groups presented, lowest prevalence of *H. pylori* was recorded in children (38.6% in children between 0-18 years), a category presenting varying prevalence values if further subdivided in smaller groups: 0-6 years - 25.8%, 7-13 years - 45.9%, 14-18 years - 42.6%. The overall prevalence value in children comes in contrast with another study, conducted in North-West Romania (8) where prevalence of *H. pylori* infection in those aged 0-18 years was 24.49%. The contrasting results could be due to different methods of testing for *H. pylori* infection. The study from North-West Romania used an invasive method of testing, the gastroscopy with biopsy collection from the gastric antrum, followed by identification of the bacterium by electron microscopy with specific staining. This method has a specificity of 95-100% (9, 10), but sensitivity is usually low. In our study we used the results of fecal antigen testing, which has a specificity of 90% and sensitivity of 88-89% (5). Another explanation for the difference in outcomes could be related to socio-economic differences between the two centers (11, 12). The higher prevalence of *H. pylori* infection in children aged 0-18 years from a center in North-Eastern Romania compared to those in the North-Western side of the country could be correlated with the lower socio-economic level of the first region. Regarding the results in adult population (over 18 years old), our study found a prevalence of *H. pylori* infection of 40.2%. By age groups, the highest prevalence was in people aged 31-40 years (54.3%). This result does not come in accordance with the literature which shows that prevalence of *H. pylori* infection increases with age, being equal to age in people over 60 years (12, 13). One explanation could be that many people over the age of 60 had already been effectively treated for *H. pylori* infection (14, 15).

Comparing the data obtained in our study with an epidemiological study performed between 1st September 2006 and 10th October 2008 (11) which aimed, among others, to identify the prevalence of *H. pylori* infection in patients admitted to a County Hospital, it can be noted that the latter study found a higher prevalence of infection (59.03%), with a maximum 78% in the 41-50 age group (11). These dissimilarities can be the result of the effective treatments performed for *H. pylori* in a large part of the population, especially following the emergence of the Maastricht V Consensus (2). Also, the *Helicopat Epid Study* reported a prevalence of 59.03%, based on the results of the urea breath test, a method that has a sensitivity and specificity of 95-97% (16). Therefore, the differences are not due to testing method for the bacterium.

Based on genders, our study did not identify significant differences (p=0.8217) between *H. pylori* infection in males (40.3%) and females (39.8%), supporting the data in the literature (1).

Regarding the environment, our study found a significantly higher prevalence (p = 0.00001) in rural areas than in urban areas, which further supports the involvement of socio-economic factors in the spread of *H. pylori* infection. Focusing on *the prevalence of infection on different*

hospital wards, there was a significantly higher number of H. pylori infections on the internal diseases ward (50.7%), while the gastroenterology ward recorded a prevalence of 41.21%, similar percentage to other wards without digestive pathologies. An explanation could be that the Department of Gastroenterology, although it has a much larger number of patients tested compared to other medical departments, has an extensive number of patients who had previously undergone effective eradication treatments. Furthermore, majority of cases admitted on the gastroenterology ward are digestive hemorrhages which can interfere with the correct identification of the fecal *H. pylori* antigen.

CONCLUSIONS

The present study conducted at Emergency County Hospital Bacău reveals a downward trend in prevalence of *H. pylori* infection in North-Eastern part of Romania, results which come close to reaching the levels of *H. pylori* prevalence found in more socio-economically advanced countries. Although the study was conducted on a limited population from one regional hospital, the decrease in prevalence of *H. pylori* infection is clearly illustrated. This can possibly be due to previous successful treatments, but also due to an increasing socio-economic level and a better understanding and application of hygiene norms amongst the general population.

NEWS

UPDATES IN GENETIC BASIS OF LYNCH SYNDROME

Lynch syndrome is a cancer-predisposing syndrome inherited in an autosomal-dominant manner, wherein colon cancer and endometrial cancer develop frequently in the family, it results from a loss-of-function mutation in one of four different genes (*MLH1*, *MSH2*, *MSH6*, and *PMS2*) encoding mismatch repair proteins. Being located immediately upstream of the *MSH2* gene, *EPCAM* abnormalities can affect *MSH2* and cause Lynch syndrome. Mismatch repair proteins are involved in repairing of incorrect pairing (point mutations and deletion/insertion of simple repetitive sequences, so-called microsatellites) that can arise during DNA replication. *MSH2* forms heterodimers with *MSH6* or *MSH3* (*MutSα*, *MutSβ*, respectively) and is involved in mismatch-pair recognition and initiation of repair. *MLH1* forms a complex with *PMS2*, and functions as an endonuclease. If the mismatch repair system is thoroughly working, genome integrity is maintained completely. Lynch syndrome is a state of mismatch repair deficiency due to a monoallelic abnormality of any mismatch repair genes. The phenotype indicating the mismatch repair deficiency can be frequently shown as microsatellite instability in tumors. Children with germline biallelic mismatch repair gene abnormalities were reported to develop conditions such as gastrointestinal polyposis, colorectal cancer, brain cancer, leukemia, etc., demonstrating the need to respond with new concepts in genetic counseling. In promoting cancer genome medicine in a new era, such as by utilizing immune checkpoints, it is important to understand the genetic and genomic molecular background, including the status of mismatch repair deficiency (Tamura K, Kaneda M, Futagawa M, *et al.* Genetic and genomic basis of the mismatch repair system involved in Lynch syndrome *Int J Clin Oncol* 2019; 24(9): 999-1011).

INTRACEREBRAL HEMORRHAGE IN SARS-CoV-2 INFECTION. CASE REPORT

INTRACEREBRAL HEMORRHAGE IN SARS-CoV-2 INFECTION. CASE REPORT (Abstract): Beyond pulmonary infection, SARS-CoV-2 can cause dysfunction of multiple other organs and system, including neurovascular complications such as intracerebral hemorrhage, about which we have now few information. We report the case of a 36-year young COVID-19 patient with intracerebral hemorrhage. As a particularity of this case, we mention the onset of coronavirus disease through a neurological manifestation, to which was later added the respiratory symptoms characteristic of SARS-CoV-2. In conclusion, we consider it important to be aware that COVID-19 patients may present with these onset findings, without initially pulmonary symptoms. Subsequent studies remain to confirm this presumed causality between intracerebral hemorrhages and COVID-19. **Keywords:** INTRACEREBRAL HEMORRHAGE, COVID-19, SARS-CoV-2 INFECTION.

In December 2019, new cases of unexplained pneumonia appeared in Wuhan (China), which later spread very quickly to other regions of China, then to Europe and also Romania, North America, and Asia. This outbreak has been confirmed as a new coronavirus infection (CoV) (1). The new coronavirus has been reported later to produce symptoms similar to those of severe acute respiratory syndrome CoV (SARS-CoV-2) (2).

Subsequently, the virus was named SARS-CoV-2, and in February 2020, the World Health Organization named the disease: coronavirus disease 2019 (COVID-19) (3). In addition to respiratory symptoms and typical clinical manifestations including fatigue, fever, cough, anorexia, throat and abdominal pain or diarrhea, neurological manifestations have been reported, with an increasing proportion of patients presenting with extrapulmonary

symptoms (3). Moreover, starting with the first months of 2020, some authors reported the increase of cerebrovascular events associated with COVID-19 (3-5), the patterns being occlusion of large vessels, venous thromboembolism, multiple territorial infarcts, raised inflammatory markers, severe systemic inflammation, younger age of presentation and antiphospholipid antibody production (6-9). On the other hand, however, the clinical features of intracerebral hemorrhage (ICH) in COVID-19 patients have been much less described (8, 10-12). The aim of this paper is to provide a clinical and imaging description of a young patient with ICH in association with COVID-19, in which the onset symptoms were extrapulmonary. We will also discuss the possible pathophysiological mechanisms and their association with the patient's neurological pathology.

CASE REPORT

A 36-year-young female without prior medical history, presents for important headache, seizures and left homonymous hemianopsia. In the emergency department, the patient was not febrile, with normal oxygen saturation and nonspecific laboratory workup. Initial head CT scan on admission and further head MR imaging showed a right temporal hematoma without other findings (fig. 1). The SARS CoV-2 PCR test performed on admission was positive.

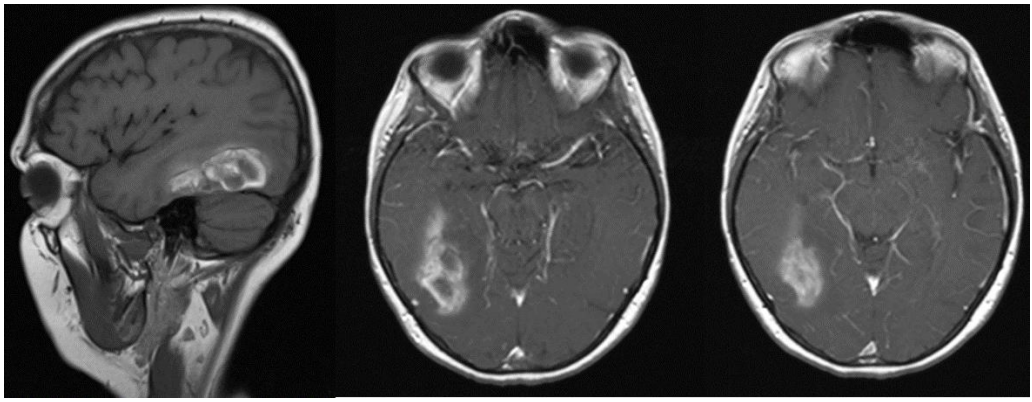

Fig. 1. Sagittal and axial enhanced T1-weighted MR imaging showing hemorrhage in right temporal lobe (*C. Toader's personal collection*)

Subsequent cerebral angiography ruled-out vascular pathology. After 12 days, the patient's neurological condition worsens, and head CT re-examination reveals increase in size of the hematoma. Urgent evacuation was carried out and no unusual brain tissue findings were reported. The postoperative evolution was good, with the appearance on the second day after surgery of dyspnea. The patient was transferred to intensive care for O_2-therapy and further management. Chest radiography and CT showed bilateral opacities consistent with multifocal pneumonia (fig. 2B and fig. 2C). The patient died a few days later, due to pulmonary complications.

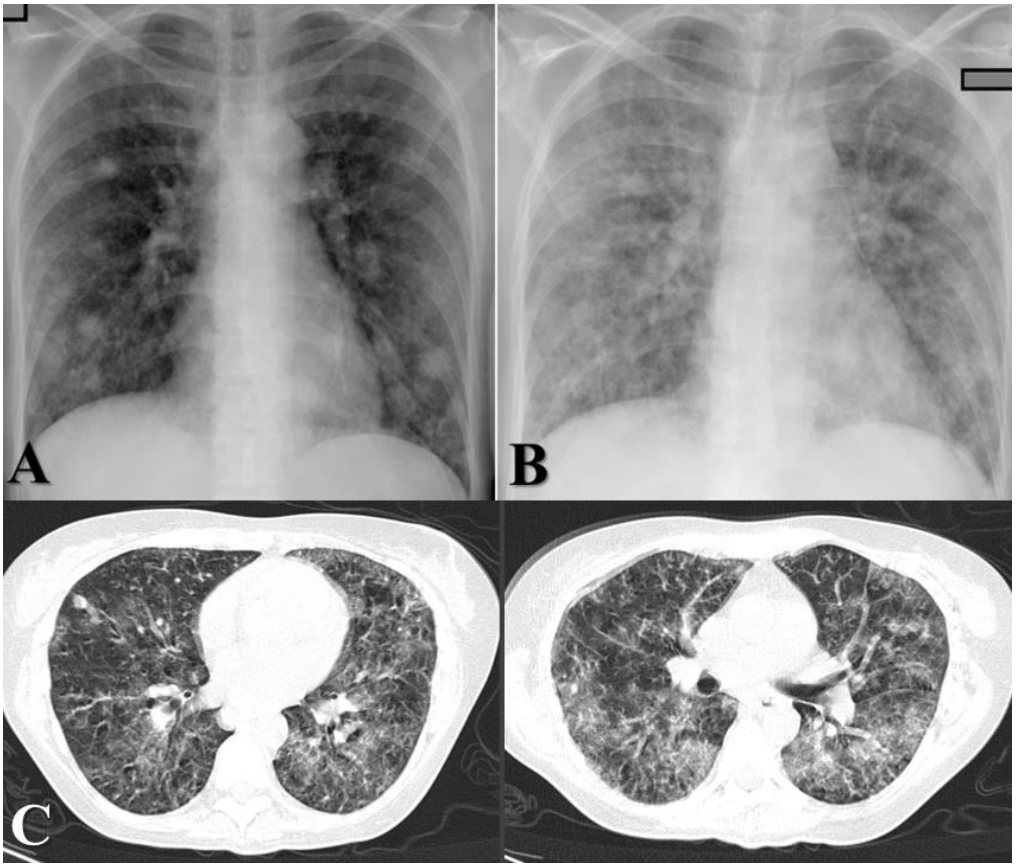

Fig. 2. Chest radiographs at 12 days (A) and at 19 days (B) after admission showing the exacerbation of bilateral pulmonary opacification; Chest CT (axial images) showing important ground-glass opacities of the lungs (C) (*C. Toader's personal collection*)

DISCUSSION

This case highlights the clinical features of a COVID-19 patient with ICH. Our patient was young, much younger than expected for conventional ICH (13, 14). In this regard, a meta-analysis that studied all types of cerebrovascular events in COVID-19 patients identified a mean age range between 45-67 years (15). Up to present, ICH in young COVID-19 patients has been reported in the literature in (16). Regarding the onset of neurological symptoms, studies reported an average delay of 32 days (range 14-38 days) between the time of COVID-19 symptoms onset and the time of occurrence of ICH. As a particularity of our case, the patient initially presented with neurological symptoms and after that the symptoms of SARS-CoV-2 disease occurred. These aspects confirm the increasing incidence of extrapulmonary symptoms at the beginning, reported in the literature (3). The location of the hematoma was lobar (fig. 1), according to some authors who reported a higher frequency of ICH in the lobar territories in COVID-19 patients (6). As in similar cases reported in the literature (6), our patient did not shown

underlying vascular abnormality on cerebral angiography. In a retrospective study of 5,227 patients with COVID-19, Altschul *et al.* observed in the 35 patients with ICH of some kind, that multi-focal and multi-compartmental ICH was more likely to be present in patients with severe pulmonary complications (17).

Although a causal link between COVID-19 and occurrence of ICH has not yet been demonstrated (17), however, numerous studies have shown that in the case of SARS-CoV-2 infection, a prothrombotic states, multi-system organ failure, cytokine storm, but also disseminated intravascular coagulopathy may occur, which would be a predisposition, at least theoretically for brain hemorrhages (3,18-20). Regarding the spread of the virus into the nervous system, two routes were considered: neuronal retrograde neurotropic route through the olfactory tract and hematogenous spread through the blood brain barrier (21, 22).

On the other hand, Benger *et al*. proposed two possible mechanisms of ICH in COVID-19 patients (6). He first considers that initial direct endothelial cell invasion occurs, and subsequently, a combination of systemic factors occurs such as inflammatory cytokine production, prothrombotic factors and activation of coagulation cascades. Ultimately, disruption of tight junction protein complexes will lead to blood brain barrier compromise and occurrence of ICH. As a second mechanism, the authors suggest that disruption of the renin-angiotensin system plays an important role in ICH in COVID-19 patients. It is well known that the renin-angiotensin system has distinct regulatory pathways in the brain, and these may be affected by SARS-CoV-2 through down flow dysautoregulation (6, 23, 24).

CONCLUSIONS

ICH in COVID-19 patients is a rare but serious way in which this new disease may manifest. It is important for neurosurgeons to become aware that patients with COVID-19 infection may present with these findings without initially pulmonary symptoms. Subsequent studies remain to confirm this presumed causality between ICH and COVID-19, as well as to determine the incidence, mechanisms, and characteristics of brain hemorrhage in COVID-19 patients.

ODONTOGENIC ORBITAL CELLULITIS. CASE REPORT AND LITERATURE REVIEW (Abstract): Orbital cellulitis, a relatively infrequent infection of the ocular adnexa and orbital adipose tissue, is an ophthalmic emergency. In the absence of prompt anti-infective treatment, the spread of the infectious process can quickly lead to serious complications: vision loss, cavernous sinus thrombophlebitis, meningitis, intracranial septic spreads, and even death. In the adult population, the frequency of orbital complications from sinus infection ranges from 0.5% to 3.9%, and that of odontogenic orbital inflammation is even more infrequent. We report the case of a 56-year-old female patient with type 2 diabetes admitted in emergency for left exophthalmos, with painful limitation of eye movements and blurred vision in her left eye (LE). Fundus examination revealed in the LE significant optic disc edema, flame-shaped peripapillary hemorrhages, and dilated tortuous retinal veins. Due to the relative subacute course of proptosis and the mild orbital inflammatory signs, the diagnostic challenge was to differentiate between orbital cellulitis and a pseudo inflammatory sign that could be associated to an orbital lymphoma or other malignancies. Imaging findings were suggestive of odontogenic orbital cellulitis. A prompt intravenous antibiotic therapy was initiated, followed by ENT surgery of the infected tooth and maxillary sinusitis. The outcome was favorable, with progressive recovery of visual function. Conclusion: Odontogenic orbital cellulitis is an ocular emergency that is best managed by a multidisciplinary team consisting of an ophthalmologist, otolaryngologist, infectious diseases specialist and neurosurgeon. Prompt multimodal therapeutic approach, including imaging investigations, antibiotic therapy, and surgical treatment can avoid serious complications and lead to full recovery. **Keywords**: EXOPHTHALMOS, ORBITAL ABSCESS, MAXILLARY SINUSITIS, ODONTOGENIC.

Orbital cellulitis, a relatively infrequent infection of the ocular adnexa and orbital adipose tissue, is an ophthalmic emergency. In the absence of prompt anti-infective treatment, the spread of the infectious process can quickly lead to serious complications: vision loss, cavernous sinus thrombophlebitis, meningitis, intracranial septic spreads, and even death. Vision loss may be due to increased intraocular pressure caused by the mass effect of the orbital infectious process, but also by direct spread of infection to the optic nerve, resulting in optic neuritis or even ischemic necrosis after staphylococcal infection.

In adults, the causes of orbital cellulitis are trauma, orbital foreign body retention, eye surgery, dacryocystitis, while in chil-

dren sinusitis accounts for about 90% of the etiology. In adult population, the frequency of orbital complications from sinus infection ranges from 0.5% to 3.9%, and that of odontogenic orbital inflammation is even more infrequent (1-3).

Clinical forms of orbital cellulitis were defined by Chandler (1) according to the severity and extension of the pathological process in: 1) preseptal cellulitis; 2) diffuse orbital cellulitis, 3) subperiosteal abscess, 4) orbital abscess, 5) cavernous sinus thrombophlebitis. Separating them based on clinical examination is difficult. However, proptosis, painful limitation of eye movement, and decreased vision are signs of severity when the infectious process progresses beyond the orbital septum. Magnetic resonance imaging (MRI) scans are particularly important in differentiating the clinical forms described by Chandler, indicating the presence of an associated sinusitis, and monitoring the effectiveness of therapy.

CASE REPORT

We present the case of a 56-year-old woman admitted in emergency for left exophthalmos, with painful limitation of eye movements and blurred vision in her left eye. She was known with type 2 diabetes mellitus and arterial hypertension. The patient declared she had some dental problems neglected due to COVID-19 pandemic. She noticed a mild protrusion of the eyeball and blurred vision about 2 weeks before presentation. As the symptoms became worse and associated left hemicrania, the patient presented to the emergency room for further diagnostic and treatment.

Ophthalmological examination revealed that the best corrected visual acuity was normal in the right eye, and 0.4 in her LE. Applanation tonometry revealed normal intraocular pressure of 16 mmHg in her right eye (RE) and slightly elevated in LE (IOP 17 mmHg (RE) and 25 mmHg (LE). The patient presented left proptosis (exophthalmometry: RE: 16 mm; LE: 24 mm), with painful limitation of eye movements, dilated episcleral veins, and mild conjunctival hyperemia. The right eye was normal.

Fundus examination revealed in the LE significant optic disc edema, flame-shaped peripapillary hemorrhages, and dilated tortuous retinal veins (fig. 1a), further confirmed by optic coherence tomography examination (OCT Zeiss). Computerized visual field testing was normal for RE and revealed peripheral nasal narrowing, and paracentral scotomas in LE (fig. 1b).

Due to the relatively subacute course of proptosis and the mild orbital inflammatory signs, the diagnostic challenge was to differentiate between orbital cellulitis and a pseudo inflammatory sign that could be associated with orbital lymphoma or other malignancies.

Laboratory investigations suggested an inflammatory syndrome: leukocytosis 12,000/mm^3, with 80.6% neutrophils, ESR 40 mm/hr., and fibrinogen 400 mg/dL.

MRI exam revealed a 27/31/32 mm poorly defined intraconal mass, located in the inferior and internal quadrant, without demarcation line with the medial and inferior rectus muscles, and with the inferior and medial orbital walls. MRI findings were suggestive of odontogenic maxillary sinusitis (fig. 3a).

The associated maxillary and left ethmoid sinusitis seen on MRI scan oriented the clinical diagnosis towards an infectious etiology. Optic nerve involvement was considered a consequence of intraorbital compression, as well as of direct extension of inflammation.

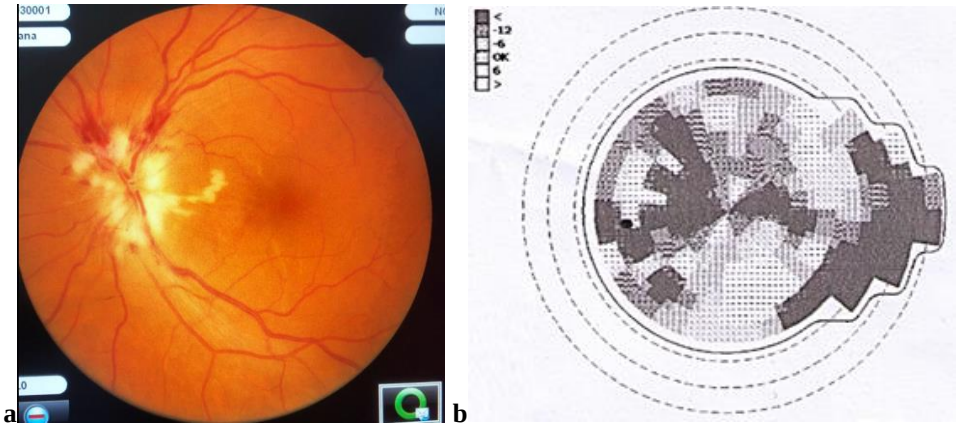

Fig. 1. a) Fundus appearance of the LE at admission;
b) Computerized visual field test (Optopol PTS-910) at admission:
multiple superior and inferior paracentral scotomas, nasal narrowing;

Fig. 2. MRI scan: a) Thickening of the left maxillary sinus mucosa with minimal fluid accumulation; thickening of ethmoid cell mucosa; fluid blockages at the level of the supraalveolar recess of the right maxillary sinus and of the left t of the sphenoid compartment; b) The pseudotumoral process encircles the optic nerve, causing mass effect and superolateral deviation. The orbital mass exhibits heterogenous pseudo nodular_contrast enhancement; diffuse edematous infiltration of the orbital fat and rectus muscles.

ENT assessment confirmed the diagnosis of odontogenic maxillary sinusitis. LE: Exophthalmos. Orbital cellulitis in observation. The treatment plan and possible com-

plications that can happen in any kind of surgery (4) were discussed with the patient and the signed informed consent was obtained (5).

General intravenous broad-spectrum antibiotic and anti-inflammatory treatment was immediate initiated: cefuroxime 3g/day and metronidazole 1g/day, and dexamethasone 8 mg/day, with slowly favorable outcome. The patient was transferred to the ENT department for the rehabilitation of sinus and dental infection foci. Surgery was performed by endoscopic approach and enucleation of the cystic transformation of the infected mucosa, evacuation of secretions from the maxillary sinus. The infected alveolar cysts were also treated surgically. Multiple biopsies were taken from the nasopharyngeal mucosa to rule out a possible lymphoma. Histopathological and immunohistochemical results showed the nonspecific reactive nature of the lymphoid infiltrates, suggestive of chronic rhinopharyngitis.

Treatment outcome was favorable, with remission of optic nerve edema and exophthalmos and recovery of visual function. At discharge visual acuity was of 0.9 in her LE and visual field examination showed the decrease in intensity and surface of paracentral scotomas. The patient was discharged with the recommendation to continue the treatment with antibiotics - cefaclor 500 mg twice daily- and with anti-inflammatory drugs - ibuprofen 200 mg/day, for 10 days, and return for follow-up visits after one week and then at one month, resulting in a progressive remission of the ophthalmological pathological findings.

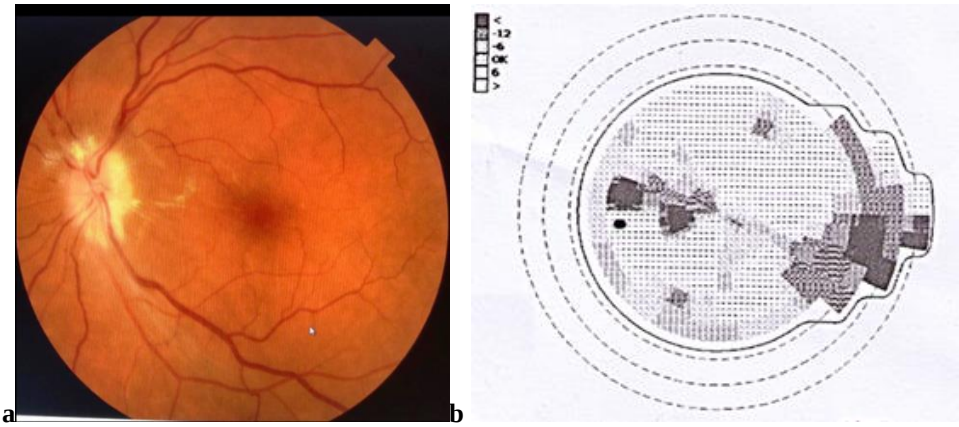

Fig. 3. a) Fundus appearance of the LE 7 days later: diminished optic nerve edema, resolved peripapillary hemorrhages; b) Computerized visual field (Optopol PTS-910): paracentral scotomas decreased in number, intensity, and size.

DISCUSSION

In the current conditions of development of antibiotic and surgical therapy, maxillary sinusitis is a condition that progresses without special complications. In most cases it is the consequence of an upper respiratory infection with *H. influenza, Pneumococcus, Staphylococcus, Streptococcus spp.* Odontogenic orbital cellulitis is a rare and severe cause of orbital infection and is associated with high risk of vision loss (2).

Orbital cellulitis most commonly occurs when bacterial infection spreads from the paranasal sinuses, most often from the ethmoid sinus. Lamina papyracea, part of the medial wall, is paper-thin and perforated by numerous foramina for nerves and blood vessels, which makes easy the contiguous spread from the ethmoid sinuses to the orbit (6). Less frequently, frontal or maxillary sinusitis can generate orbital septic complications by spreading the infection through the floor, respectively the orbital ceiling. Another mechanism described by Rothschild *et al.* (7) is that the infection spreads through the maxillary sinus, the canine fossa with a thrombophlebitis of the angular vein or the pterygopalatine fossa and infra-temporal fossa both reaching the orbit by means of the inferior orbital fissure. The involved flora is mixed, consisting of aerobes and anaerobes, and the diversity of flora and the presence of anaerobes in maxillary sinusitis increase with age (1, 8). Commonly reported bacteria in orbital abscesses include *Staphylococcus aureus, Staphylococcus epidermidis, Streptococci, Diphtheroids, Haemophilus influenza, Escherichia coli,* and multiple species including aerobes and anaerobes. Li et al. (9) reported a case of necrotizing orbital cellulitis secondary to odontogenic *Streptococcus constellatus*. The presence of *methicillin-resistant staphylococci* has been found in a relatively large number of cases, reason why these germs must be considered as possible infectious agents when planning antibiotic therapy.

Therapeutic management should be initiated urgently when orbital cellulitis is suspected, due to the formidable complications, such as acute vision loss, cavernous sinus thrombosis, or septic intracranial dissemination (7-15). High-dose intravenous antibiotic therapy will be initiated with broad-spectrum, Gram-positive, Gram-negative, and anaerobic antibiotic combinations. Analgesics such as NSAIDs and acetaminophen can be used alone or in combination to achieve effective pain control in patients with orbital cellulitis (16).

The most commonly used therapeutic combinations are vancomycin (15 to 20 mg/kg per day IV every 8 to 12 hours) + second or third generation cephalosporins (Ceftriaxone 2 g per day IV) + metronidazole (500 mg IV or orally every 8 hours) (1, 2, 16-18). In case of cephalosporin allergy, fluoroquinolones may be used (Ciprofloxacin 400 mg IV twice a day, levofloxacin 500 mg IV twice a day). There are no controlled trials to define the ideal duration of antimicrobial therapy in orbital cellulitis or when to switch to oral from intravenous treatment (16). Therapy is initiated intravenously and can be continued orally after at least 3-5 days, in case of favorable clinical course, in the absence of fever and signs of decreased inflammation and proptosis. Oral antibiotic therapy options are cephalosporins or combinations of penicillin + beta-lactamase inhibitor.

Surgery may be indicated in cases with poor response to medical treatment and imaging evidence of orbital abscess. According to Harris and Garcia (19), the indications for surgical approach must consider the location of the orbital abscess, visual status, presumed response to antibiotic therapy, sinus involvement, and the risk of intracranial spread of infection. The main indications for surgery are compromised vision by retinal and optic nerve lesions, large abscesses or extensive superior or inferior abscesses (that might not resolve quickly, even if sinusitis is medically cleared) and increased risk of intracranial complications. After the initiation of intra-

venous antibiotic therapy, surgery may be necessary if there is no improvement after 48-72 hours, suggesting that bacteremia is not responding to the choice of antibiotics or relative afferent pupillary defect develops (20). Streptococcus spp can cause necrotizing lid disease and systemic manifestation such as fatal streptococcus toxic shock syndrome, with multiorgan failure, even in previously healthy subjects. The virulence is related to the production of M proteins and exotoxins A and B, that mediate tissue necrosis by causing massive release of cytokines (18), such as tumor necrosis factors and interleukins, as general biomarkers of inflammation.

Imaging of the orbit and eye are extremely useful in the differential diagnosis of optic disk edema, including angiofluorography with dyes like sodic fluorescein and indocyanine green – now a wide-open used dye, in many surgical specialties, including general surgery (21), documenting a possible sinus origin of the infection and the presence of complications. In these cases, a multidisciplinary approach is required, with dental extraction, trans alveolar drainage, and ENT surgery of the infected sinuses.

COVID-19 pandemic has a deep impact on the social and economic life worldwide and is considered the most severe sanitary crisis since the Spanish flu, a hundred years ago (22). In the present case, diabetes, the delayed dental treatment due to the fear of getting infected with COVID-19, as well as the relative delays in getting appointments to specialized outpatient clinics, in the presence of insufficient and incomplete antibiotic self-medication caused the development of a torpid infectious process (23). imposed the differential diagnosis with an orbital malignancy, particularly an orbital lymphoma.

The management of anti-infective therapy in a diabetic patient has particularities. Blood-sugar levels are more difficult to control during the infectious process, associate a higher risk of complications, sepsis including, and the response to usual therapy may be altered (24, 25). The arterial hypertension is a frequent associated condition with diabetes, leading in early phases to issues of differential diagnosis of the flame shaped retinal hemorrhages and mild optic disk edema.

CONCLUSIONS

Odontogenic orbital cellulitis is an ocular emergency that is best managed by a multidisciplinary team consisting of ophthalmologist, otolaryngologist, infectious disease specialist, and neurosurgeon.

Prompt multimodal therapeutic approach, including imaging, antibiotic therapy, and surgical treatment, can avoid serious complications and lead to full recovery.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

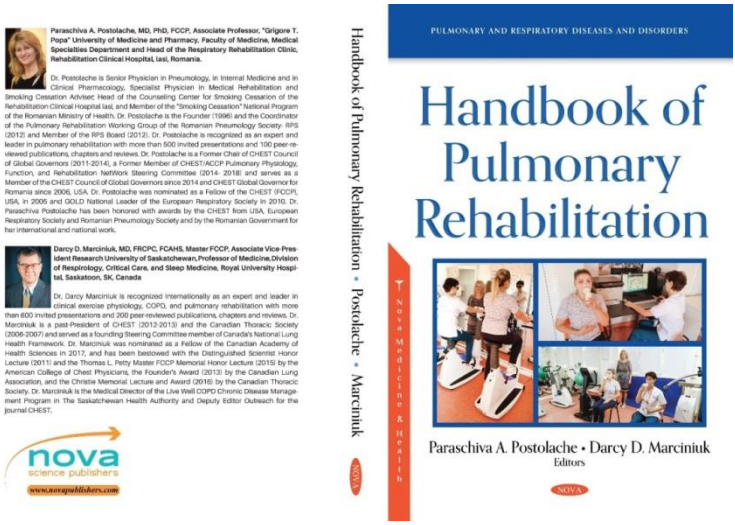
BOOK REVIEW

HANDBOOK OF PULMONARY REHABILITATION

Editors: Paraschiva A. Postolache (Romania), Darcy D. Marciniuk (Canada)
Nova Science Publishers, Inc., New York, USA



In the conditions of the current COVID-19 pandemic, we welcome the publication of the volume: Handbook of Pulmonary Rehabilitation, an editorial novelty for Romania. The idea of this volume has crystallized in the last 20 years of intense activity in this field of Associate Professor Dr. Paraschiva A Postolache. The manual for the rehabilitation of the patient with respiratory diseases is a reference work, which places pulmonary rehabilitation, a fundamental part of patient management, in the wider framework of the sick human body. The book emerged as a necessity for the management of chronic lung disease whose incidence is constantly increasing worldwide and at the right time in the current context of COVID-19 disease pandemic, for which this therapy is essential.

Pulmonary rehabilitation is not a completely new concept, but this book is the first to focus on the quality of life of the patient, not only on the medical act itself and its safety. In the last three decades, pulmonary rehabilitation has become a cornerstone in the comprehensive management of COPD and other chronic lung diseases, on a solid physiological basis, as a result of extensive scientific evidence, randomized controlled trials, meta-analyzes and guidelines. Pulmonary rehabilitation is today an extremely important tool of treatment, a source of information for respiratory pathophysiology, but has also added therapeutic methods and measuring tools in patient care. We focus on the future !

The volume provides a scientific and practical framework for all those involved in the care of the chronic lung patient, pulmonologists, geriatrics, family physicians, nurses, physiotherapists, nutritionists, social workers, occupational therapists, psy-

chologists and bioengineers. Those interested have access to all the elements necessary to set up a Clinic or Department of Pulmonary Rehabilitation.

The two editors of the Handbook, Assoc. Prof. Dr. Paraschiva A. Postolache (Romania) and Prof. Dr. Darcy D. Marciniuk (Canada) coopted a team of internationally renowned specialists in the field of pulmonary rehabilitation and related medical fields.

Assoc. Prof. Dr. Paraschiva A Postolache has a rich international activity, being President of the CHEST Council of Global Governors and member of the CHEST Board of Regents from 2011 to 2014, member of the Steering Committee of the Pulmonary Physiology, Function and Rehabilitation Network of the American College of Chest Physicians (ACCP)/CHEST between 2014 and 2018 and member of the CHEST Council of Global Governors since 2014 and CHEST Global Governor for Romania since 2006. Dr. Postolache has been nominated as a Fellow of CHEST (FCCP), USA, in 2005 and National Leader GOLD of the European Respiratory Society (ERS) in 2010, being honored with awards granted by CHEST (U.S.A.), ERS (Europe), the Romanian Society of Pneumology (Romania) and the Romanian Parliament, for its international and national activity. Dr. Postolache is the founder (1996) and Coordinator of the Respiratory Rehabilitation Working Group of the Romanian Society of Pneumology, being recognized as an expert and leader in pulmonary rehabilitation.

Dr. Darcy D. Marciniuk is a University Professor in Canada and has a focus on pulmonology, critical care and sleep medicine. Dr. Marciniuk is also the medical director of the Chronic Disease Management Program: COPD Live Well. Dr. Marciniuk is internationally recognized as an expert and leader in the exercise physiology, chronic obstructive pulmonary disease (COPD) and lung rehabilitation, with over 420 international guest presentations and 200 peer-reviewed publications, chapters and reviews (Google Scholar H-index 51). Dr. Marciniuk is former President of CHEST (2012-2013) and the Canadian Thoracic Society (CTS) (2006-2007) and President of the International Respiratory Society Forum. He served as a member of the founding Steering Committee of the National Lung Health Framework of Canada (2007-2011) and a member and chair of the Royal College of Physicians and Surgeons of Canada and the Pulmonology Examination Committee (1999-2007). Dr. Marciniuk has been the lead author of three clinical practice guidelines in COPD, published by CTS, a member of the International Group of Clinical Practice Guidelines in COPD (ACP/ACCP/ATS/ERS), Cardiopulmonary Stress Testing (ATS/ACCP), pulmonary rehabilitation (ATS/ERS) and prevention of acute exacerbations of COPD (CTS/CHEST), as well as in many clinical practice guidelines for the management of COPD, published by CTS. As an associate vice president of research, he led the development of the University of Saskatchewan's international plan and currently chairs the institution's pandemic response and recovery team. Dr. Marciniuk is a member of the Canadian Academy of Health Sciences and deputy editor (Outreach) for CHEST Journal. He was awarded the Distinguished Scientist Honor Lecture (2011) and Thomas L. Petty Master FCCP Memorial Honor Lecture (2015) by the ACCP, Founder's Award (2013) by the Canadian Lung Association, Christie Memorial Lecture and Award (2016)) by the CTS and the Distinguished Researcher Award (2013) by the University

of Saskatchewan.

The book was reviewed by Prof. Dr. Nicolino Ambrosino, M.D., FCCP, from the University of Pisa, Italy, Editor-in-Chief of the Italian Journal of Pulmonology, Consultant Researcher at Maugeri Clinical Institutes, Pavia, Italy, international expert in lung rehabilitation and awarded by the ERS for educational merits; Prof. Dr. Panagiotis Behrakis, M.D., Ph.D. (McGill), FCCP, Greece Pulmonologist - Intensivist, Athens Medical Center, Director, Institute of Public Health, American College of Greece, Principal Investigator of the Biomedical Research Foundation of the Athens Academy, Associate Professor at the Universities of Athens and Harvard) and Prof. Dr. Mihai Berteanu ("Carol Davila" University of Medicine and Pharmacy, Bucharest; Head of the Medical Rehabilitation Clinic at the "Elias" University Emergency Hospital; President of the Specialized Commission of Physical Medicine and Rehabilitation of the Ministry of Health and Delegate of Romania to UEMS-PRM).

The book has 24 chapters, 410 pages, reviewing the fundamentals and the practical applications of pulmonary rehabilitation. After a short history of pulmonary rehabilitation internationally and in Romania, are presented the general aspects of pulmonary rehabilitation, then the specific aspects of complex evaluation of patients to be included in the program, correct pharmacological therapy, smoking cessation, followed by aspects practices of education, nutrition, psychotherapy, ethics, prescribing the lung rehabilitation program with emphasis on the training of general and respiratory muscles, saline therapy, telerehabilitation, robots and artificial intelligence, all for returning to the socio-professional environment as early as possible, etc. The following are particular aspects of pulmonary rehabilitation in other chronic lung diseases besides COPD, including COVID-19 disease, the last chapter addressing the future of pulmonary rehabilitation.

Among the authors we highlight Prof. Dr. Nicolino Ambrosino, from Italy. Prof. Ambrosino, in the chapter on Telemedicine and Rehabilitation, highlighted that there is a great potential of telerehabilitation to reduce existing barriers for patients to have easy access, and in any conditions, to the pulmonary rehabilitation programs, such as there are also in the current COVID-19 pandemic, that there are still many barriers to the expansion of telerehabilitation and that research to date has not explored the true effectiveness of telerehabilitation.

A new methods of pulmonary rehabilitation is the training of respiratory muscles, approached by Oliver Christian Göhl, Ph.D., from Germany, Executive member of the Board of Directors of "AG-Lungensport in Deutschland eV", Member of the Scientific Advisory Board of "Selbsthilfegruppe Mailingliste Lungenemphysem COPD Deutschland eV" and "Deutsche Emphysemgruppe e.V.", Eicklingen, Germany and the Romanian team consisting of Paraschiva A. Postolache, Gabriela Jimborean, Edith Simona Ianosi and Mioara Szatmary. The training of the respiratory muscles, independently or associated with the respiratory rehabilitation program, has the effect of reducing the symptoms, increasing the capacity for effort and the quality of life, being achieved with different types of devices and techniques.

Rehabilitation can be applied starting from the newborn, useful information can be found in the chapter "Rehabilitation of infants with chronic neonatal lung disease according to clinical guidelines" of the Romanian team: Andreea Avasiloaiei and Maria Stamatin, continued in children with

chronic lung diseases, extremely important aspects being addressed by Prof. Dr. Paul H. Sammut from U.S.A. and then to adults, the most important aspects related to this subject being developed in the rest of the 24 chapters, which address the newer aspects, according to the international guidelines, of the pulmonary rehabilitation.

Also noteworthy is the chapter addressing the role of pulmonary rehabilitation in surgical lung diseases written by Prof. Dr. Francis J. Podbielski from U.S.A., patients undergoing surgery to reduce lung volumes, with operable lung cancer or lung transplant requiring pre- and postoperative lung rehabilitation for a correct and complete management, with remarkable results anywhere in the world.

Ethical aspects of the application of pulmonary rehabilitation at all ages (Cristina Gavrilovici and Liviu Oprea from Romania and Teodora Manea from UK), return to the socio-professional environment (Ioana Soare, Romania) and future directions of pulmonary rehabilitation (Paraschiva A. Postolache and Andreea -Daniela Meca from Romania and Darcy D. Marciniuk from Canada, co-editor of the book) point out the current trends in lung rehabilitation around the world.

This book provides a theoretical and practical scientific framework to help mainly the students and residents, the future medical practitioners, but also the specialists. The pulmonologist, explorationist, geriatrician, family doctor, nurse or physiotherapist, nutritionist, social worker, occupational therapist, bioengineer, psychologist, etc., all interested in alleviating the suffering of the chronic lung patient, now have access to all the elements necessary to establish a Clinic or Department of Pulmonary Rehabilitation.

The Handbook of Pulmonary Rehabilitation for patients with respiratory diseases has a contemporary, holistic multidisciplinary approach. This comprehensive reference book places pulmonary rehabilitation, a fundamental part of the complex management of patients, in the wider framework of the sick human body, in all its aspects. In the 24 chapters, the book includes new sections on the development of rehabilitation as a global discipline and new aspects of the results of pulmonary rehabilitation, such as socio-professional reintegration. Older approaches to nutrition, psychotherapy, etc. were reconsidered because they also interfere with the patient's well-being in the rehabilitation process.

Pulmonary rehabilitation has hardly been imposed among effective therapeutic methods, but now its place is well established, and the treatment of the chronic respiratory patient can no longer be conceived without the integration of rehabilitation, as is currently practiced in most centers in the developed world.

The book was published by Nova Science Publishers, Inc., New York, one of the most important scientific, technical and medical publishing houses in the world, founded in 1985 by Frank Columbus, with over 1,800 titles published annually. It is considered the second largest multidisciplinary publisher in the world, based on BKCI coverage from 2005 to 2012.

Dante Alighieri (1265-1321), often simply called Dante, was an Italian poet, writer and philosopher of Tuscany. His famous work, "Divine Comedy", originally called Comedia and later christened "Divine" by Giovanni Boccaccio (1), is widely considered one of the most important works of the Middle Ages and the greatest literary work in Italian; thus, we can say that the work "Divine Comedy" is the nucleus around which the Italian language crystallized, as we know it today (2).

Dante is known for promoting and establishing the use of the vernacular Italian language in literature at a time when most of his publications were written in Latin, which was accessible only to educated readers. "De vulgari eloquentia" (On eloquence in vulgar language) was one of the first literary appearances of the Italian vernacular. The use of the Tuscan dialect for works such as "New Life" (1295) and "Divine Comedy" helped to form and concretize what is the standardized Italian language today. His work set a precedent that would be repeated by important Italian Renaissance writers such as Petrarca or Boccaccio.

Dante played a key role in the formation and establishment of Italian literature. He is considered the "father" of the Italian language, and in Italy he is often called il Sommo Poeta ("Supreme Poet"). Dante, Petrarca and Boccaccio are considered to be the "three crowns" of Italian literature. His literary descriptions of Hell, Purgatory, and Evil have inspired the next generation of artists and writers, especially influencing Western literature. He is considered a source of influence on English writers such as Geoffrey Chaucer, John Milton and Alfred Tennyson, among many others; moreover, the use of a form of rhyme (third rhyme) with three interlaced lines is dedicated to him (3).

Dante Alighieri was born in the Republic of Florence, Tuscany, Italy around 1265. This can be deduced from the autobiographical allusions in the "Divine Comedy". The

first book, Hell, begins, "Nel mezzo del cammin di nostra vita" ("In the middle of our life's journey"), suggesting that Dante was about 35 years old, if we look at the average lifespan of that period, of 70 years; and since his imaginary journey into the world of hell took place in 1300, he was most likely born around 1265. Some verses in the "Paradiso" section of the "Divine Comedy" also give a possible indication that he was born in Gemini sign, because in that year, the sun was in Gemini between about May 11 and June 11.

Dante claimed that his family had its roots in ancient Rome (Hell, XV, 76), but the most distant member of the family he could remember (Paradiso, XV, 135) was Cacciaguida degli Elisei (Italian crusader, foreigner Dante's great-grandfather), born around 1100. Dante's father, Alighiero di Bellincione, was affiliated with the "white Guelph" political movement but did not suffer significant retaliation after the Ghibellines were victorious in the Battle of Montaperti of the middle of the 13th century). This suggests that Alighiero and his family had a certain prestigious social status; although some sources indicate otherwise, the fact that Alighiero, politically inactive, was so fallen that he was not considered worthy of being sent into exile or punished (4).

Politically, Dante and his family were loyal to the Guelphs, a Florentine political alliance that had the support of the papacy and was in opposition to the alliance of the Ghibellines, the latter being supported by the Emperor of the Holy Roman Empire. Regarding Dante's family, his mother, Bella, came from the Abbati family, and there is not much information about her influence on Dante, because she passed away when Dante was less than ten years old. After his mother's death, Dante's father, Alighier, remarried a woman, Lapa di Chiarissimo Cialuffi. Some sources indicate that he did not formally marry, he grows with it, because during the Middle Ages the remaining widows were socially limited in this respect; but it is certain that their relationship resulted in two children, Dante's sister and half-brother, Tana and Francesco, respectively (Gaetana) (5).

Related to the main muse of Dante's creation, Beatrice, he relates that he first met Beatrice Portinari at a very young age, about eight or nine years old, mentioning that he fell in love with her at first sight, without having to at least talk to her. Unfortunately, at the age of only twelve, the young Dante was promised in marriage by his father, a marriage that would take place with Gemma di Manetto Donati, a descendant of the powerful Donati family. Dante relates in his writings that he had frequent meetings with Beatrice on the streets of Florence, meetings that were limited to some exchanges of formal greetings; he never got any closer to Beatrice.

Following these encounters, about eight to nine years after his marriage to Gemma, Dante dedicated several sonnets to Beatrice, but none to Gemma - which he does not even mention in his writings of this kind. Many other details about Dante's marriage to Gemma are missing, but we can say for sure that the marital relationship between the two resulted in three children - Pietro, Antonia and Jacopo (6).

In order to have the right to participate in public life, Dante had to be a member of one of the many craft / trade guilds in Florence, so he became a member of the guild of doctors and pharmacists. In the years following this affiliation, he occasionally participated by speaking or by voting in certain councils of the city-republic of Florence from that

period. Due to the irreversible damage or loss of some of the archives of the meetings between 1298-1300, years in which Dante was an active member of the republican councils, we cannot appreciate the true extent of Dante’s participation in public life in those years.

There is not much relevant information about the education Dante received as a child; most likely he studied in a Florentine church / monastery school or at home. From his work, more precisely from Purgatorio - XXVI, we know that he greatly appreciates Tuscan poetry and the compositions of the Bolognese poet Guido Guinizelli, calling the latter his “father” during the period when the Sicilian Poetic School was gaining as much ground as possible. cultural-artistic scene from the Tuscany region. Moreover, he was passionate about the poetry of Daniel Arnaut, as well as the great old classics of antiquity, such as Virgilius and Ovid.

The relationship between Dante and his muse, Beatrice, was representative of “courtly love”, an unshared love whose socio-emotional characteristics were first cataloged in French poetry of the eleventh and thirteenth centuries. Dante’s emotional experience with such love was typical, but its expression in his work was completely unique. In the name of this love, Dante left his mark on dolce stil novo (“the sweet new style”, a term that Dante himself coined) and would join other contemporary poets and writers to explore aspects of love that were never stressed (7). Love for Beatrice (as Petrarch would express it for Laura, but somewhat differently) would be his leitmotif; and more, for the reason of living, together with political passions. In many of his poems, she is described as semi-divine, constantly watching over him and giving spiritual instructions. When Beatrice died in 1290, Dante sought refuge in Latin literature. Convivio reports that he read “De consolatione philosophiae” by Boethius and “De Amicitia” by Cicero.

He then devoted himself to philosophical studies in religious schools, such as the Dominican one in Santa Maria Novella. He took part in the disputes that the two great mendicant orders (Franciscan and Dominican) held publicly or indirectly in Florence, the former explaining the doctrines of the mystics and St. Bonaventure, the latter explaining the theories of St. Thomas Aquinas (8).

At the age of 18, Dante met Guido Cavalcanti, Lapo Gianni, Cino da Pistoia and, in a short time, Brunetto Latini in Florence; together they became the leaders of dolce novo style. Later, Brunetto received a special mention in the Divine Comedy (Inferno, XV, 28) for what he had taught Dante: his eminent comrades. About 50 such poetic commentaries, known as Rime, have been published, much of which are included in Convivio and Vita Nuova.

Like much of the citizens of Florence at that time, Dante took part in the political conflict between the Guelph and Ghibelline factions; participating in the Battle of Campaldina in 1289 on the side of the Guelphs, and later to join Charles of Anjou in 1294. In the current situation, in order to continue his political activity and public life, Dante became a pharmacist, but without intend to practice this trade. (He was forced to make this professional choice because a law that came into force in 1925 required the nobility, who wanted to have such activities, to belong to a guild within the “Corporazioni delle Arti e dei Mestieri”). As a politician he did not have an exhaustive activity, but he managed to hold important positions during his years of activity; considering also the extremely unstable political context from

that date (9).

Following the victory over the Ghibelline faction; the Guelph faction suffered a schism that led to the formation of two new political factions - the White Guelphs (to which Dante would join) and the Black Guelphs (a faction patronized by Corso Donati). Separated at first only on dynastic lines, schims began to deepen ideologically, especially on papal influence in the internal and external affairs of the Republic of Florence. The White Guelphs wanted to achieve higher gradients of independence from the pope, implicitly from Rome, while the Black Guelphs supported the papal faction and satellite approach to Rome. As a result of these ideological differences, the White Guelphs managed to emerge victorious, initially exiling members of the rival faction in Florence.

Following these events, Pope Boniface VIII launched a military campaign against the Florentine Republic, culminating in the military occupation of the city; despite peace efforts through Carol de Valois (brother of the King of France at the time) - named pacifier of the conflicts in the Tuscan region. (1301) The city council chooses to delegate Dante to Rome in an attempt to negotiate with the Papal authorities (10).

Arriving in Rome with the delegation of the White Guelphs, Dante is asked by the Pope to stay with him in Rome, dismissing the other delegates sent with Dante. While Dante was with the Pope in Rome, Florence was attacked by Black Guelph forces, led by Carol of Valois; As a result of these actions, most of the white Guelphs in Florence are killed or exiled. A new government takes over the city, led by Cante dei Gabrielli da Gubbio, a government that accuses Dante of corruption (by joining the White Guelph faction) and forces him into exile for two years, along with a fine. The new government will also accuse Dante of financial evasion during his tenure as city prior (1300). Fortunately, the Pope, although a supporter of the Black Guelphs, suggests that Dante stay in Rome to avoid the repercussions he would suffer if he returned to Florence; In the months that followed, Dante was declared a deserter by the city-state authorities (11).

Next, Dante refused to pay a fine, firstly because he considered himself innocent of all the purely politically motivated accusations brought against him, and secondly because he could not afford to pay it, all his possessions remaining in Florence, confiscated. by the Black Guelphs. Thus, he was sentenced to life in exile; if he dared to return to Florence without paying a fine, being in danger of being executed. In 2008 - almost 700 years after the great writer's death - the city council of Florence decided to annul Dante's sentence by a motion of annulment.

In the years following his sentence, Dante continued to participate in numerous attempts by the White Guelph faction to retake the city and regain its leadership, unfortunately all these attempts failed, most often due to betrayals within the faction. Disappointed by all this, he decides to give up any kind of political affiliation, disgusted by the vile behavior of both his enemies and his allies; thus, he swears that he will never again be politically affiliated with any faction (12).

He was to be the guest of Moroello Malaspina, between the years 1306-1307, at Lunigiana. At the end of his stay in Lunigiana, he left as a guest of Bartholomew I in Verona, then continued his journey to Liguria, where he settled in Sarzana. He is about to set off again, this time for Lucca, where

he will meet a woman - Gentucca - who will help him settle there for a while. (He mentions it showing his gratitude in Purgatory, XXIV). Other sources indicate that he visited Paris (1308-1310), some even speculating that it reached Oxford, England - statements taken from Boccaccio’s book; book published a few decades after Dante’s death. Most of these speculations can be justified by the admiration of readers in France and England at that time who were impressed by Dante’s writings. In Dante’s Immensa Dei dilentione testante to Henry VII of Luxembourg, he indicated his residence as in the region of the Arno springs, near the region of Tuscany - 1311. Regardless of the multiple residences in which he was, it is certain that the works of the great Sommo Poets were influenced by exile, which now had much more time to deepen philosophy, history, poetry and prose; his literary and cultural interests becoming much more prominent in this period of his life (13).

Henry VII of Luxembourg entered Italy in 1310, along with more than 5,000 soldiers; on hearing this news, Dante sees in him a new Charlemagne who will reunite the Tuscan region with the Holy Roman Empire, thus bringing to Florence the glory of yesteryear by removing the Black Guelphs. In this sense, Dante will personally write to Henry and more Italian princes and rulers, thus hoping to help liberate the city of Florence.

Henry attacked Florence and defeated the Black Guelphs in 1312, but Dante did not participate directly in this battle; largely due to the fact that he was no longer affiliated with the White Guelphs. Unfortunately, Henry died shortly after this victory, just a few months later, in 1313, and with his death came the death of Dante’s last hope of seeing Florence again. On his return to Verona in 1313, Cangrande I will offer him shelter and security to lead a relatively prosperous life; Dante later mentioning it in Paradiso XVII (14).

The politico-military agitation continued in Florence, in 1315 Ugoccione della Faggiuola took over the city and demanded a general amnesty for those in exile, including Dante, but the government of Florence still demanded that he pay a very large fine. Dante refused to pay this fine, choosing to remain in exile. Moreover, Ugguccione changed Dante’s death sentence, provided he came to the city and declared that he would never enter Florence again. Again, Dante completely refused this orphanage, and his death sentence would be extended to his sons. He still hopes late in life that he will be able to return to Florence on honorable terms (15).

The last days of the life of the “father” of the Italian language are spent in Ravenna, where he lived since 1318, being the guest of Prince Guido gives him Polenta. Dante Alighieri dies of malaria (which he contracted in Venice) on 14 September 1321, at the age of 56; his three children, most likely his wife, Gemma, and many of his admirers from neighboring towns attended the funeral. He was buried in Ravenna, at the Church of San Pier Maggiore (now called the Basilica di San Francesco). In 1483, the praetor of Venice, Bernardo Bembo, erected a tomb for Dante Alighieri (16).

On the tomb, a verse by Bernardo Canaccio, a friend of Dante, is dedicated to Florence: *“Parvi Florentia mater amoris”.*

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

NEWS

MIDGUT VOLVULUS - DIAGNOSIS AND TREATMENT

Midgut volvulus is a complication of malrotated bowel, can occur at any age but most frequently appears within a month of birth. Typically, the neonate is entirely normal for a period before suddenly presenting with bilious vomiting. Plain radiographs can appear normal, can reveal bowel obstruction, double bubble sign or pneumoperitoneum. Gastrointestinal contrast study can identify the volvulus, the malrotation and sometimes can spontaneous perform reduction of the volvulus. Ultrasound findings include clockwise whirlpool sign, abnormal superior mesenteric vessels, dilated fluid-filled loops of small bowel, free intra-abdominal fluid. CT is often performed in older patients, in which presentation is non-specific and will depict whirlpool sign of twisted mesentery, malrotated bowel configuration, inverted SMA/SMV relationship, bowel obstruction, free fluid or gas. Urgent surgical repair (Ladd procedure) is required to prevent ischemia or to resect infarcted bowel loops. If resection is performed stomas are usually created. In some instances, surgical fixation of the duodenum and cecum may be performed although it is unclear if this is of benefit in preventing recurrence. Normal anatomical positioning is not achieved; the duodenum and small bowel remain on the right, and the cecum and colon are on the left side of the abdomen. (B Rasuli, F Gaillard, *et al*. FORMULATION AND STUDY OF RECTAL IBUPROFEN MUCOADHESIVE HYDROGELS Abstract): The rectal route represents an alternative to oral administration in pediatrics. Ibuprofen is a non- steroidal anti-inflammatory agent, used in all age groups to reduce pain, fever, and inflammation. **Aim:** to develop and characterize ibuprofen-containing mucoadhesive rectal gels. **Material and methods:** Carbopol 940, sodium alginate, and low viscosity hydroxypropyl methylcellulose HPMC were used as gel-forming agents and propylene-glycol and glycerin as permeation enhancers. 5% of ibuprofen was incorporated in all formulations. Three gels have been prepared containing 1% Carbopol, 0.5% Carbopol and 5% HPMC, and 5% sodium alginate. The influence of formulation variables on the pharmaco-technical parameters (adhesivity, pH, and diffusion) was studied. The amount of API released through the membrane using a Franz cell in the acceptor media was measured. Mathematical models were applied to model the release of the active substance. **Results:** The pH of gels ranged between 4.2-5.0. Viscosity varied between 165 and 212 mPas. The detachment force was from 0.02 to 0.12 N. All three gels were formulated suitable for children and adults. **Conclusions:** The obtained experimental results showed a superior release of ibuprofen from the 5% sodium alginate gel. **Keywords**: IBUPROFEN, RECTAL GEL, ADHESION, FRANZ CELL.

The oral route presents the main route of administration for all age categories. For children (from birth to 16 or 18 years) an alternative administration route is rectal, having a series of advantages such as avoiding swallowability and taste problems and administration for vomiting or unconscious children (1). This population group needs specific formulation to meet their needs in concordance with age-specific development (cognitive and motor skills). Challenges also may be associated with this administration route; patient education is a key factor to better acceptance. The rectal route may be used for both, local and systemic effects. Rectal formulations have systemic effects intended to treat pain, fever, nausea, vomiting, allergies, depression, and reflux (2-6).

Rectal pharmaceutical forms present bioadhesion, the adhesion of biological tissue, and a pharmaceutical form (7), pre-

senting enhanced bioavailability (8). Rectal gels present type 3 bioadhesion (9), an interaction between a mucin surface and a polymer. Mucoadhesive substances are characterized by numerous hydrophilic groups.

Polymers like Carbopol - polyacrylic acid, hydroxypropyl-methylcellulose (HPMC), and sodium alginate present carboxylic or hydroxyl groups and are included in the category of excellent bioadhesion properties (10). In contact with water, these polymers tend to swell, forming bonds with the mucosa (10, 11).

Ibuprofen, a propionic acid derivate, is a widely prescribed anti-inflammatory drug among pediatric patients for its antipyretic and analgesic effect (12). It is the most prescribed drug for pain and inflammation (13) being available as a prescription and over-the-counter drug (14) and approved for children above the age of 3 months (15). Ibuprofen figures on the Essential Drug List of the World Health Organization (16). It is a non-selective inhibitor of both cyclooxygenase enzymes COX1 and COX2 and is mainly metabolized by the liver (17).

Our study aims at the formulation and characterization of ibuprofen, as an active pharmaceutical ingredient (API), containing rectal gels. As gel formers, Carbopol 940, sodium alginate, and low viscosity HPMC were used. Propylene-glycol and glycerin were used as permeation enhancers. 5% of ibuprofen was incorporated in all formulations.

MATERIAL AND METHODS

Ibuprofen was a kind gift from BASF (Germany). Carbopol 940 was purchased from Lubrizol (USA), sodium alginate from FoodINC (China), and low viscosity HPMC JRS Pharma (Germany). Sodium hydroxide, ethanol, and glycerin were from Chemical Company (Romania). Propylene-glycol used was from Scharlau Chemie SA (Spain).

Table I presents the composition of the three formulated gels.

TABLE I.
Gel compositions

Component	Amount (g)			Role of component
	F1	F2	F3	
Ibuprofen	5	5	5	API
Ethanol	10	20	10	API solvent
Carbopol 940	1	0.5	-	Gel forming agent
Sodium Hydroxide solution 10%	0.4	0.2	-	Neutralizer for Carbopol
Sodium alginate	-	-	5	Gel forming agent
HPMC LV	-	5	-	Gel forming agent
Propylene-glycol	2	2	2	Penetration enhancer
Glycerin	10	10	10	Hydrating agent
Distilled water	71.6	57.5	68	Solvent

Gel preparation method. Ibuprofen was dissolved in ethanol. The Carbopol 940 gel was prepared by polymer hydration and neutralization with NaOH 10% solution. Sodium alginate and HPMC were hydrated at room temperature with water. Glycerin and propylene-glycol were added followed by homogenization. As the last step, the

dissolved ibuprofen was incorporated.

Consistency was determined using a manual *penetrometer* (VEB Feinmess Dresden) equipped with a penetration cone. The penetration rate was recorded in mms. The penetration depth was measured at room temperature. *Extensometry* was measured as the surface covered by 1 g of gel after the addition of increasing weights. *Viscosity* was determined with a Fungilab Viscolead Adv apparatus using an R4 stem, completely emersed in the sample at room temperature.

Evaluation of adhesive properties Adhesion strength was measured, in terms of the force needed to detach gels with an in-house assembled apparatus. Samples were introduced into a tubular cell with a semi-permeable membrane. The balance system determined the mass needed to detach the sample from the cell. The detachment force was calculated as F= Gxg, where G is the necessary mass for detachment and g=9.81 m/s^2. The maximum adhesive forces were the average of three measurements.

pH measurement: 25 mL solutions were prepared by dissolving 1.0 g of gel in distilled water. The pH value of each sample was measured after 10 minutes at 25°C using a pH meter (Consort C831 multi-parameter analyzer).

In vitro release study

Used apparatus: Franz cells (Perme-Gear, Germany), clear jacketed with flat ground joint, 14 mL receptor volume, pinch clamp, and stir bar. The acceptor phase was phosphate buffer pH 7.4, maintained at 37°C±1°C. From the acceptor compartment of the Franz cell, samples of 1.0 mL were withdrawn at 15 minutes for a period of 2 hours. The acceptor phase was immediately replaced with fresh phosphate buffer also maintained at 37°C ± 1°C. Hydrated Teknokroma nylon membrane (0.45 µm thickness, 25 mm diameter) was used.

The released amount of ibuprofen was determined with a UV spectrophotometer (Shimadzu UV 1800, Japan) at 273 nm wavelength.

Mathematical modeling of drug release was realized with the DDSolver Add-In Program, Microsoft-Excel software by model-dependent methods (18). Model-dependent analysis was performed with 4 most used models (tab. II) for hydrogels (19).

Mathematical models and equations

No.	Mathematical model	Equation
1.	0 order kinetic	$F=k_0*t$
2.	First order kinetic	F=100*(1-Exp(-k1*t))
3.	Higuchi	F=kH*t^0.5
4.	Korsmeyer-Peppas	$F=k_{KP}*t^n$
F= % dissolved active ingredient at time "t"; k = release constant;		

RESULTS AND DISCUSSION

The obtained hydrogels are homogenous, semisolid preparations (fig. 1). F3 is colored in light yellow brown.

The texture of the hydrogels is influenced by the gel-forming agent. The highest spreadability was observed for F3, based on sodium alginate. Adding low viscosity HPMC to the Carbopol-based hydrogel modified spreadability. Penetration depth had a maximum of 13 mm for F3 (fig. 2).

Fig. 1. The appearance of the three formulated gels (A - F1, B - F2, C - F3)

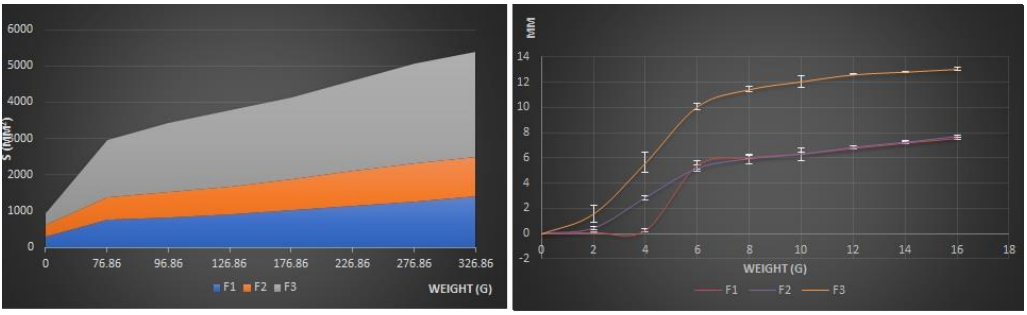

Fig. 2. Consistency measurement (extensometry and penetration)

F1 and F2 have closed pH values, for F3 pH are slightly higher. The adhesion force confirms the findings of consistency evaluation, values are closed to each other for the two Carbopol-based gels, and HPMC addition increased the detachment force. Viscosity values show the same pattern (tab. III).

Drug release had been followed for 120 minutes in a phosphate buffer at pH 7.4. After 120 minutes in all cases above 8% of ibuprofen was released. F3 hydrogel released the maximum amount of API (fig. 3).

Mathematical modeling of the diffusion profiles intends to characterize and explain drug release from the hydrogel matrix. Of the most used four models the highest R^2 values were observed in the case of the Korsmeyer Peppas model (with values over 0.98). The Korsmeyer-Peppas constant of the mathematical model describes the diffusion from the gel and n is the release exponent. If n is above 0.5, a non-Fickian drug diffusion takes place. In our case n is above 0.790 for all formulations, meaning that ibuprofen can diffuse through the hydrogel mesh, probably because it's smaller than the mesh size (tab. IV).

TABLE II.I

pH, adhesion force, and viscosity values

Formulation	pH	F (N)	Viscosity (mPa)
F1	4.72	0.104	212
F2	4.84	0.124	234
F3	5.00	0.026	165

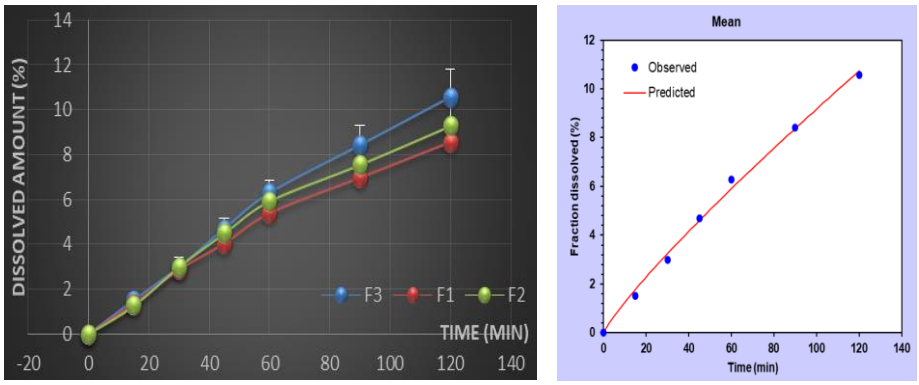

Fig. 3. Release profiles of the three hydrogels and the best fit model for F3

TABLE IV.
Values of the mathematical models

Mathematical model	Parameters	F1	R^2_adj	F2	R^2_adj	F3	R^2_adj
0 order kinetic	K_0	0.077	0.9691	0.084	0.9673	0.093	0.9862
First order kinetic	K_1	0.001	0.9757	0.001	0.9757	0.001	0.9909
Higuchi	K_H	0.693	0.9265	0.753	0.9183	0.828	0.9004
Korsmeyer-Peppas	K_{KP} and n	0.198 and 0.790	0.9946	0.207 and 0.799	0.9894	0.173 and 0.863	0.9954

F1 and F2 hydrogels are both Carbopol 940 based, probably, presenting similar mesh sizes, and similar released drug amounts. Sodium alginate hydrogel presents a superior drug release after 120 minutes, but also a disadvantage of poor mechanical strength and possible microbial contamination (19).

CONCLUSIONS

Hydrogels are versatile drug delivery systems for several administration routes. These highly hydrated networks enable the rectal administration of small molecules, such as ibuprofen. 5% API (100 mg ibuprofen in 2 g or 200 mg in 4 g of hydrogel) is intended for children, but also suitable for adult patients. The formulated mesh networks presented suitable consistency, viscosity, pH, and adhesion force for rectal administration. A superior release of ibuprofen from the 5 % sodium alginate gel was determined, the release is non-Fickian.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and this work was supported by the "George Emil Palade" University of Medicine, Pharmacy, Science and Technology of Targu Mures, Research Grant No. 10127/15/17.12.2020.

CENTENARY OF THE BIRTH OF PROF. Dr. DOC. GRIGORE TEODOROVICI

Dana Baran, E. Târcoveanu, A. Ivan
"Grigore T. Popa" University of Medicine and Pharmacy Iasi

"*May the human model illustrated by Professor Grigore Teodorovici remain always present in the memory and tradition of the Iași medical school*."
Valeriu Rusu

The Society of Physicians and Naturalists of Iași, its publications and first collaborators

In 1830 "The Society of Physicians and Naturalists of the Principality of Moldavia" (SPN) was founded in Iași as a *Medical Reading Circle*. It was the first scientific association in the Romanian Countries, "the first European academy of the national spirit" or, according to Gustav Otremba, "the oldest Medical Society in the Orient". The activity of this Society took shape through: the establishment of the first medical and naturalistic library which contained materials of great documentary value (1830); the creation of the first Museum of Natural History (1834); the establishment of the first botanical garden in the Romanian Principalities (1856); promotion in Moldavia of economic and technological progress, including industrialization, but especially modernization of agriculture; this latter was due to Ion Ionescu de la Brad, organizer of model farms, remarkable statistician and professor of agriculture, who, in 1841, obtained the first Romanian champagne. As early as 1835, SPN initiated the first group scientific expeditions to explore flora, fauna, minerals, hydrologic and spa resources of Moldavia (Slănic Moldova spa resort was also scientifically analyzed). SPN supported pioneering geological (Repedea) and archaeological (Cucuteni) studies. It also contributed to the establishment of the first medical-military institutions, such as hospitals (1831) and a scientific association. SPN purchased a telescope in order to set up the first astronomical observatory (1850). It strove for national emancipation and Union of the Principalities (1859) and was directly involved in the foundation of pre-university and university institutions, including the establishment of the Faculty of Medicine in Iași (1879). Concurrently it stimulated the use of the Romanian language in science. SPN supported the medicalization process of the country, stimulating sanitary organisation, Western European type of medical and pharmaceutical assistance and health education. In the SPN history, the appearance of the first medical-pharmaceutical, economic and agricultural popularization publications in Romanian edited by a scientific society can be considered one of its most important achievements. The first attempts date back to 1844 illustrated by "The Advisor of Health and Economics. Periodical leaflet for the Romanian People" (*Povățuitorul sănătății și a economiei.*

Foaie periodică pentru poporul românesc), followed, in 1851, by the „*Leaflet of the Society of Physicians and Naturalists of the Principality of Moldavia*" (*Foaia Societății de Medici și Naturaliști din Principatul Moldovei*), both under the direction of Dr. Costache Vârnav. Since 1859, *The Society of Physicians and Naturalists of the Principality of Moldavia* turned into *The Society of Physicians and Naturalists of Iași*, being integrated into the young State of the United Principalities.

On November 28th, 1886, owing to the efforts of several hearty doctors and naturalists, most of them members of the teaching staff of the University of Iași (Faculty of Sciences and Faculty of Medicine), the decision was made to be published, both in Romanian and French, "*The Bulletin of the Society of Physicians and Naturalists of Iași*", intended to contribute to the dissemination of modern knowledge from the various fields of science and to the publication of papers authored by members of the Society. At the same time, it was meant to render Romanian research known in foreign countries and enable the exchange of the publication of the Society of Physicians and Naturalists with periodicals from abroad.

The appearance of the "*Bulletin of the Society of Physicians and Naturalists of Iași*" since *January 1, 1887,* which, from 1924, changed its name to "*The Medical-Surgical Journal of Iași. Bulletin of the Society of Physicians and Naturalists*" (French title: "*Revue médico-chirurgicale de Jassy / Bulletin de la Société des Médecins et des Naturalistes*"), generated by the increasingly rich academic life and the permanent interest of the Iași intellectuals in the development of a climate favorable to research activities. The existence of the SPN periodical has continued to this day, with some interruptions, due to the two World Wars, polarizing around it valuable collaborators from Iași, from all the medical centers of the country, as well as from abroad.

Since its early years, in the editorial board of the *Journal* one could always find prominent scientific figures of Iași, professors at the city University: the chemist Petru Poni, the geologist Grigore Cobălcescu, the philosopher Vasile Conta, the physiologist Leon Cosmovici, the parasitologist Nicolae Leon, Dr. Anastasie Fătu, Dr. Aristide Peride, Dr. Eugen Rizu and many others. Over the years, other great medical figures of Iași and SPN presidents, like Professors Ioan Ciurea, Emanoil Riegler, George Bogdan, Ernest Juvara, Constantin Bacaloglu, Constantin I. Parhon, Nicolae Hortolomei, Vasile Rășcanu, Mihai Ciucă, Alexandru Slătineanu, Grigore T. Popa, Gheorghe Tudoranu, Ion Nicolau, Alexandru Moruzi, Gheorghe Năstase, Iuliu Nițulescu, Ion Enescu, Theodor Economu, Nicolae Bumbăcescu, Gheorghe Popovici, contributed, through *The Medical-Surgical Journal* (*Revista Medico-Chirurgicală*), to the advancement of medical sciences, amplifying the torch of creative thought and multidisciplinary research (1).

Regrettably, the instauration of communism in Romania immediately after Second World War, caused the suppression of both *SPN* and *The Medical-Surgical Journal* from 1948 to 1956.

Academic milestones in the life of Professor Dr. Doc. Grigore Teodorovici (1922-1992)

Studies and beginning of his career

Among our contemporaries, it is appropriate to pay posthumous tribute to the

personality of Professor doctor docent Grigore Teodorovici, the longest-serving editor - over 30 years - of *The Medical-Surgical Journal*, the one who played an essential part in preserving its continuity and in maintaining its prestige. During its existence of 126 years *"The Society Bulletin"* (later called *"The SPN Medical-Surgical Journal")* was the forum for the most advanced ideas of the time, being appreciated in national medicine as a periodical of high standards and scientific rigor.

Grigore Teodorovici was born one hundred years ago, on April 15th, 1922, in Faraoanele commune, Vrancea County (2). He went through all the stages of pre-university education of the time, after which he attended the courses of the Faculty of Medicine of the University in Iași (1942-1948), during a difficult period that covered World War II. He was possibly also counseled and supported by one of his uncles, a famous surgeon. From the beginning he attracted attention due to his dedication to the profession he chose. He started his career in microbiology as a IVth year student, at the "Alexandru Slătineanu Bacteriological Institute". In 1946, after the refuge, the young demonstrator (*preparator)* participated in the regrouping of the Iași medical school. By then research and practice were synchronized with Western science in the creative spirit of the national school of bacteriology, virology inframicrobiology, infectious diseases, hygiene and epidemiology represented, among others, by Professors Mihai Ciucă, Petru Condrea, Ion Nicolau, Constantin Bart, Ion Alexa, Alexandrina Gaiginschi, Maria Franche, Dumitru Cornelson. In 1952, under Prof. Condrea's direction, the Iași branch of *Dr. Cantacuzino Institute of Serums and Vaccines* in Bucharest was inaugurated, and particularly efficient drugs started to be synthesized (vaccines, immunostimulants – such as *Polidin*).

Directly or indirectly, most of these scientists belonged to the Cantacuzino school of microbiology and the same was true for Professor Teodorovici. Endowed with a remarkable intelligence, with a thirst for knowledge and for deepening scientific truths, from an early age Dr. Teodorovici was noticed and appreciated by his teachers, particularly by the eminent and demanding Professor Dr. Petru Condrea. Consequently, on June 19, 1948, he was appointed assistant professor of microbiology.

The Antibiotics Factory in Iași and industrial microbiology

Educated in his Master's laboratory, Teodorovici became an elite bacteriologist, being concerned, among other things and among the first specialists in our country, with the issue of antibiotics: biosynthesis, purification and dosage, bacterial resistance (3). Recommended by Condrea, from 1952 to 1954 Dr. Teodorovici gave microbiology courses to the biologists of the Antibiotics Factory in Iași, which opened in 1955. Head of the microbiology section of the *Institute for Antibiotic Research* from 1957 until 1960, he trained the first industrial bacteriologists, and contributed to the production of the first batch of Romanian penicillin G, the first such antibiotic obtained in South-East Europe as well (3). All his life he remained connected to this pioneering Romanian Factory, where he was a professor and a permanent adviser on the problems of industrial microbiology. He intuited that the excessive use of antibiotics would generate bacterial mutants and recombinants, further leading to multiple bacterial resistance. Hence the stalemate of

antibiotic therapy was to be soon reached. Among the first, he paid attention to nosocomial infections that he generally characterized as "infectious hospitalism".

From Microbiology to Epidemiology

In 1959 he left the chair of Bacteriology for the vacant chair of Epidemiology, feeling attracted to this discipline, which, thanks to his work and talent, soon became the most appreciated in the country. Teacher, scientific researcher in the laboratory of this department, practical guide of the medical and sanitary structures in the counties of Moldavia, author of interesting articles in the field of epidemiology that have kept their validity until the present times, Dr. Teodorovici developed and consolidated prophylactic medicine in Moldavia, becoming a model for the entire country. He strengthened the team spirit, cooperating with all those who could intervene in the prevention and combat of epidemic diseases that, at the time, occurred almost in a chain, one after another, on the territory of Moldavia: exanthematical typhus, typhoid fever, diphtheria, malaria, meningitis, tularemia and Q fever and others were present. Gifted with initiative and organizational skills, Professor Teodorovici was much admired by his coworkers at the Iași Institute of Hygiene and Public Health, at the Sanitary-Antiepidemic Centers (CSAs) on the territory of Moldavia, at the "Isolation" Hospital for Contagious Diseases in Iași and at other hospitals in the territory, because, at the time, he managed to control the entire specific activity, identifying and containing the spread of epidemics in Moldavia.

In 1961, together with Prof. Dr. Eugenia Duca, he highlighted the *Friedlander's pneumobacillus* multiple resistance to all antibiotics used by then and its frequency in children hospitals. Another critical situation emerged in 1968, when Prof. Teodorovici, fruitfully cooperating with Prof. Dr. Eugenia Duca, proved, for the first time worldwide, the nephritogenic capacity of *Streptococcus zooepidemicus* (2). Teodorovici's epidemiological surveys and diagnoses were flawless. Similarly, in 1970, he epidemiologically and clinically diagnosed an outbreak of enterovirosis that subsequently laboratory tests confirmed to have been caused by *Coxsackie B6* virus. Interestingly, Prof. Teodorescu's very accurate methods for assessing sensitivity and specificity indexes of diagnostic efficacy were internationally validated only eight years later by Ransohoff and Feinstein (3).

Promoting teamwork and understanding the interdisciplinary nature of epidemiology, Prof. Dr. Doc. Grigore Teodorovici carried out successful long-term collaborations with various disciplines of the Institute of Medicine and Pharmacy (today, the University of Medicine and Pharmacy) from Iași, such as those coordinated by Prof. Dr. Alla Vâţă, Prof. Dr. Mihai Duca, Prof. Dr. Eugenia Duca, Prof. Dr. Gheorghe Zamfir, Prof. Dr. Lucia Alexa, Prof. Dr. René Duda, or Prof. Dr. Marcel Burdea, a famous pediatrician.

At the Iași Institute of Hygiene and Public Health, he worked with famed specialists, like, Dr. Nicolae Constantinescu, Dr. Olga Zavate, Dr. Copel Bercovici, but he also cooperated with renowned physicians from various health directions or Antiepidemic Sanitary Centers (CSA) of Moldavia, such as Dr. Constantin Oană, Dr. Ioan Buzdugan, Dr. Gheorghe Brebenel (2).

At the same time, he cooperated with the *Cantacuzino Institute of Sera and Vaccines* and the *Institute of Inframicrobiology* (today: *Ștefan S. Nicolau Institute of Virol-*

ogy) in Bucharest, as well as with epidemiologists specialized in agricultural, veterinarian and military issues. The discussions or debates initiated by Prof. Teodorovici were real lessons, always animated by comradeship and proceeding in harmony.

Grigore Teodorovici's School of Epidemiology in Iași

Thus, Prof. Dr. Grigore Teodorovici created a valuable school of epidemiology, and with his skills, goodwill and proverbial friendship, he attracted worthy collaborators who, over time, became his professional followers and successors: Prof. Dr. Aurel Ivan and Prof. Dr. Doina Azoicăi, who preserved the prestige of the Department of Epidemiology, reaching, on a didactic, scientific and practical level, the measure of their training Master.

Grigore Teodorovici, a sensitive man, lover of art, music and of the city of Iași, also encouraged and helped young artists to accomplish their career. Rodica Postolache, professor of French and acknowledged visual artist, is among them.

Professor Teodorovici had a noteworthy publishing activity, too. In 1950, using Professor Condrea's typed notes, as well as some materials from the similar university departments in Bucharest and Cluj, along with those of his coworkers, Prof. Teodorovici already set up the "engine" for the appearance of the first didactic material of Bacteriology and Virology, in three lithographed volumes, which remained available to students for more than half a century. The following year, in 1951, he contributed to the appearance of the first notebook of "Practical Works" which, in 1957, was edited by the Medical Publishing House in Bucharest. The treatise on *The Epidemiology of Transmissible Diseases* published in 1978 - the first on this topic in the country - illustrated a reference material for specialists for a very long time. In 1981, *The Epidemiology of Non-Communicable Diseases* was printed at the Bucharest Medical Publishing House - once again, a national priority -, with Prof. Dr. Grigore Teodorovici and his close disciple and successor at the chair, Prof. Dr. Aurel Ivan, as coauthors. The same year, the work entitled "Guidelines in Contemporary Epidemiology" was published at Junimea Publishing House in Iași.

He was a prominent teacher and a demanding researcher, with an impressive accuracy and intuition of the epidemic phenomenon, qualities that imposed him as a high-class expert among his specialist colleagues in the country and abroad. He was a role model for many doctor generations, he valued his direct collaborators, and was a supporter of interdisciplinary activities, addressing the most important and difficult community health problems. In this framework, the lifetime tandem he formed in 1959 with Professor Mihai Duca, in studying the epidemiology of influenza and acute respiratory infections, led to theoretical and practical research, followed by publications of great value, which determined the establishment, in 1964, at the Virology Department of the Institute of Medicine and Pharmacy from Iași of the "World Health Organisation National Center for Influenza Surveillance". Its investigations yielded reference results (3).

He also directed postgraduate education in preventive medicine in Iași (1972-1976). In fact, for a while, he also led the Institute for the Improvement and Specialization of Doctors and Pharmacists that belonged to the Institute of Medicine and Pharmacy of Iași.

University Professor Dr. Doc. Grigore Teodorovici and *The Medical-Surgical Journal*

Academician Prof. Dr. Vasile Râșcanu, the personality who in 1948 saved from extinction both The Society of Physicians and Naturalists and its periodical, which was later edited by Professor Dr. Teodorovici, signed in the first issue of ***The Medical-Surgical Journal*** from 1956, the article "The historical-scientific significance of *The Medical-Surgical Journal* of Iași", being aware that its success will only be real if the journal could prove its vitality. That was why, in his capacity as editor-in-chief, Prof. Rășcanu worked with an extremely strong editorial team, made up of two assistant chief-editors - Professors Șerban Brătianu and Vladimir Bușureanu -, four editorial secretaries and 50 members of the editorial board, all outstanding specialists. The results were to be seen in a short time: the four issues of the *Journal* in 1956 gathered 1,097 pages, constituting the most productive year in the entire history of the publication.

Starting with first number of 1960, Professor Grigore Teodorovici was appointed *editorial secretary*, and the *Journal* became his own life. In 1966, ten years after the resumption of the post-war publication, in the editorial "Ten years after", the balance sheet of *The Medical-Surgical Journal* looked incredible: 20 million pages had been printed, there were 2,000 annual subscriptions due to exchanges with 44 countries, 157 foreign journal titles were received. Over time, the noblest goal of the Society of Physicians and Naturalists, already formulated in the draft statute from 1832, was happily fulfilled: "To follow the progress of the medical sciences and to contribute as much as possible to them".

The Journal evolved both quantitatively and qualitatively. In 1971, thanks to Dr. Teodorovici, the first color advertisement for antibiotics appeared in the SPN Journal, and starting with second number of 1972, when he became deputy editor-in-chief, Prof. Dr. Doc. Grigore Teodorovici improved the publication's graphics and created the first color cover, in a formula that has been maintained to this day (3).

Professor Dr. Doc. Grigore Teodorovici was the one who determined the fate of the Journal, as he required value and originality for all accepted articles, but he also had to be very careful about the censorship of the time. He was an innate editor, devoted to the Journal, a fact that was evident by the way he cared about the quality of the articles various authors submitted. He reworded unclear or confusing sentences, sometimes rewrote entire passages, improving the scientific style of medical articles, all from his passion for science and professional responsibility. He solicited innovative articles from his contributors gifted with writing he trained himself, systematically trying to mobilize them, either through letters or personal discussions.

With frequent materials - documents on the history of medicine being published in the *Journal*, he equally promoted the evocation of traditions of the Iași medical school. He got involved in the celebration of 100 years of University medical education in Iași in 1979, co-authoring four articles included in the *Proceedings of the Scientific Sessions* (volumes I and II). Two focused on historical aspects: "Representative figures and stages in the field of hygiene and epidemiology at the Institute of Medicine and Pharmacy of Iași" and "The development of postgraduate education at the Institute of Medicine and Pharmacy of

Iasi". Two others pointed out epidemiological studies and surveys the Institute of Medicine and Pharmacy of Iași successfully supported: "Research directions in the epidemiology of transmissible diseases on the territory of Moldova. Twenty years of experience" and "Contributions of the Institute of Medicine and Pharmacy in Iași to the problem of bacterial etiology in the diarrheal disease in children of the young age group". He revered his surviving Masters whom he continued to ask for advice sometimes. Professor Ion Alexa was one of them.

Another hard part was working in the printing house. A special relationship was created between the Professor and the typesetters, since he conquered them with the bonhomie, gentleness, and kindness he showed to these persons whom he respected and helped every time they needed it.

With no. 1 of 1975, Prof. Dr. Doc. Grigore Teodorovici was appointed *editor-in-chief* of the periodical and did not part with the *Journal* until his death. In 1980 he coauthored a short history of the Society of Physicians and Naturalists (4) and in November 1986 - January 1987, he had the chance and joy to celebrate, in an anniversary issue (*Rev Med Chir Soc Med Nat Iași, Supplement 1986*), 100 years since the appearance of the periodical of the *Society of Physicians and Naturalists of Iași* on January 1, 1887. This supplement summed up the whole centennial history of the SPN periodical, and at the same time reflected the evolution and specific involvement of the SPN members and collaborators over the decades. Concurrently, on November 28, 1986, a plenary session, reuniting all the scientific sections of the SPN, took place at the SPN headquarters in Iași.

Professor Teodorescu's editorial duties spanned the communist era from 1956 to 1990, when, as paradoxically as it may seem today, *The Medical-Surgical Journal* went through a scientifically flourishing lapse of time (1). Its post-war period was one of "transition and reaffirmation" (6).

The whole medical university life in Iași and Moldavia revolved again around the Society and its publication, *The Medical-Surgical Journal*, whose prestige and role had increased significantly. The Society's projects were now mainly aimed at epidemiological actions, hygiene and public health whereas the other specialized sections encompassed the medical, surgical, pediatric, pharmaceutical and dental fields. The auxiliary health personnel, students gathered in two distinct sections. The *Journal* was not limited to university staff alone. Besides, it tightly synchronized to the evolution of medical education in Iași: the establishment of The Institute of Medicine and Pharmacy after 1948, with its Faculties - General Medicine, Pediatrics, Hygiene, Pharmacy and Dental Medicine - and closely mirrored new directions of medical education, research and assistance. Communication sessions of various types were mainly carried out within the Society and in its historical headquarters. In 1992, a supplement to the *Journal* appeared briefly, belonging to the SPN student section, formally established in 1974, which redefined itself in September1991 (6).

As an editor-in chief, Prof. Dr. Doc. Grigore Teodorovici understood his mission was to continue all his predecessors' efforts and adapt the publication to his day: «During the 100 years since the appearance of its first issue, the "Bulletin of the Society" later entitled "*The Medical-Surgical Journal*" - became the tribune of the most advanced ideas of the time, being appreci-

ated in the national and world scientific life as a periodical of high-quality and scientific rigor. In fact, in 1932 the Hygiene Section of the League of Nations considered "*The Medical-Surgical Journal* of Iași" as one of the "great medical publications"»… "In the last 30 years, the medical periodical from Iași experienced a very special development. Today, due to its rich and varied content, as well as technical editing conditions, it ranks alongside important and prestigious scientific publications from the country and abroad. In the current conditions of the development of medicine in Iași, *"The Medical-Surgical Journal"* reflects - first of all - the scientific concerns of the departments and circles of *"The Society of Physicians and Naturalists"* and of the teaching staff of the Institute of Medicine and Pharmacy in Iasi, their thinking and experience, the best results of national scientists, as well as the trends in contemporary medicine".

In the pages of the *Journal,* various sections are inserted, the content of which is closely related to the realities and progress of medical and pharmaceutical sciences: general reports, studies on different topics, medical news, practical medicine notes, letters to the editor, medical chronicles, the graduate forum, syntheses of some scientific manifestations, reviews. A number of articles signed by Romanian or foreign physicians are published in widely circulated languages" (1). Professor was satisfied with his work: "…our *Journal*… is accepted for exchange by over 275 periodicals from 43 countries, being sent for review and indexed by 22 publications and institutions specialized in this direction" (1).

Unfortunately, after only five years since the *Journal* centennial, severely ill, Prof. Dr. Doc. Grigore Teodorovici corrected the issues 1-2 of the 1992 *The Medical-Surgical Journal* on his hospital bed, the spirit of responsibility being a *modus vivendi* for him. His passing away in 1992, came as a shock to everyone, including the regular contributors to the publication he had led so dedicatedly for so many years. The consequences stemmed out immediately: from 240 pages, included in the first issue of the Journal in 1991, with a circulation of 1,500 copies, in no. 1 of 1993 dropped to 156 pages and to a print run of 800 copies.

Contemporaries' Tribute to Professor Grigore Teodorovici

In 2002, 10 years after his disappearance, fourteen prominent members of the Iași medical academic community, who knew him closely, commemorated him and authored laudatory articles in Supplement 1, to no.1, vol.106 of *The Medical-Surgical Journal* of the mentioned year (May 24th , 2002) (3).

Of these 14 personalities, only two are still alive, but the stories of all of them continue to testify until today lesser-known aspects of Professor Dr. Doc. Grigore Teodorovici's life, activity and time.

We retain a few appreciations and memories recorded at that moment, for their pertinent observations regarding Professor Dr. Teodorovici's personality.

Prof. Dr. Aurel Ivan: "For all of us, those who knew him and valued him for the way in which he gave himself with all his being to his work and family, Prof. Dr. Doc. Grigore Teodorovici will forever remain a role model teacher, researcher, animator of *The Medical-Surgical Journal* and Romanian epidemiology. His long and efficient didactic and scientific activity

along with his guidance of the epidemiological network of the Moldavian counties, as well as his service as editor-in-chief of *"The Medical-Surgical Journal",* placed forever Prof. Dr. Doc. Grigore Teodorovici, amongst the prominent people of the "Grigore T. Popa" University of Medicine and Pharmacy of Iași, from Moldavia and from Romania" (3).

Prof. Dr. Doc. Alla Vâță: "Professor Grigore Teodorovici dedicated himself to epidemiology, while remaining faithful to microbiology, which was his life's passion. The treatise on *The Epidemiology of Communicable Diseases* published in 1978 (the first in the country) was a reference material for specialists. He was generous to all collaborators, sharing with them his theoretical knowledge and his rich experience as an epidemiologist. Clear mind, he quickly grasped the essence of the epidemiological phenomena he studied. He wrote with great ease in a style as clear as his mind. As editor-in-chief of *The Medical-Surgical Journal*, with national and international circulation, he contributed to the appearance of this periodical, being concerned with maintaining the prestige of this representative publication for the research activity of the Iași university medical center" (3).

Prof. Dr. Dumitru Buiuc: "I was attracted by the passion and dedication with which he worked. I followed his extensive epidemiological investigations in which there was no winter, no summer, no distances. In the heat of the summer or in the whirlwind of the blizzard, he was always on the road: from Brodina in the Bucovina Obcine to Câmpuri in the Vrancei Mountains; between two roads he was always engaged in teaching activities, processing data from field and laboratory investigations, receiving friends in the evening and the collaborators with whom he was thinking about other and other investigations. He edited, issue after issue, *The Medical-Surgical Journal* that was so dear to him" (3).

Prof. Dr. Valeriu Rusu, former Editor-in-chief of *The Medical-Surgical Journal* and Dean of the Faculty of Medicine: "The Journal was his very life. Professor Grigore Teodorovici was the main author of the entire Journal for so many years. Through his scientific work, he contributed to the evolution of Romanian epidemiology. In an article *"Guidelines to contemporary epidemiology"* from no. 1/1968, new ideas concerning epidemiology were mentioned, including the study of non-infectious diseases, and the new methodology was clearly defined: its clinical, experimental, epidemiological basis. We recognize there the contours of what today is evidence-based medicine" (3).

Prof. Dr. Doc. Gheorghe Zamfir: "Having a special training in general medicine and also mastering, along with epidemiology, the fields of microbiology and virology, as well as those of general hygiene and social medicine, Prof. Dr. Doc. Grigore Teodorovici was able to respond, with particular effectiveness, to the multiple episodes and epidemic conjunctures that our province was constantly haunted by"... "An aspect of Prof. Teodorovici's activity, to which, all his lifetime, he paid particular attention was that of editor of *The Medical-Surgical Journal of Iași*. In this respect, Prof. Teodorovici identified himself with the Journal in such a way that anyone who uttered the words *"The Medical-Surgical*

Journal" meant Prof. Teodorovici. Carefully and extremely meticulously, the Professor checked every paper intended for publication, regardless of the profile (internal medicine, surgery, pediatrics, gynecology, hygiene), detecting with amazing ease any typographical or any other type of error. For this *Journal*, Prof. Teodorovici had collaborators who work hard and contributed to the prestige of the *Journal* (Gheorghe Popovici, Gheorghe Scripcaru, Traian Baran, Mihaela Groll, *et al.*)" (3).

Dr. Ioan Buzdugan: "The perfect combination of his literary and oratory talent, with a remarkable ability to synthesize scientific and practical results in the fields of laboratory, clinic and prophylactic actions, were concretized in "postulates" for modern Romanian epidemiology, so that through his presence at the University of Medicine and Pharmacy in Iași, he commanded the appreciation and respect of other university collectives in our country and even abroad... Through his exceptional efforts, *The Medical-Surgical Journal of Iași* experienced a new period of editorial and scientific glory, while he was the coordinator of this secular medical periodical of Iași" (3).

Prof. Dr. Gheorghe Scripcaru: "In the field of scientific research that he affirmed as a teacher, as well as Editor of the oldest scientific journal in the country, he expressed the conviction that you are not a convincing teacher if you do not participate in creating the science you teach, if you don't live in it, if you don't lead a common life with science, so as not to become a simple science hunter, as Grigore T. Popa said. He thus achieved the initial desire of *The Medical-Surgical Journal* to rely on the University's point of view, as science should be. The rigor of verifying and validating scientific truth was for him a cure for any disappointments, probably also a solution to despair, weapons with which he defeated the risk of easy satisfaction."

Prof. Dr. Traian Baran: "Professor Teodorovici's name came, thus, in the end, to be identified with a prosperous period in the long and arduous life and survival of *The Medical-Surgical Journal*, a period of stability, in which exchanges with over 300 similar publications on a world level definitely meant an apogee. And this, in an era when the flow of information of any kind was constantly viewed as a potential danger and systematically restricted. The constant updating of the Journal, along with the care for the representation of all the Faculties and Disciplines of the University, all the research groups, the acceptance and invitation of external collaborators, the quality of the inserted materials were priorities of the editors and, in this regard, Professor Teodorovici's discernment and tact in relations with colleagues, with people in general, his understanding, his gentle but firm character, morality and spirit of justice played a decisive role."

The message of testimonies

Professor Teodorovici undoubtedly strengthened the prestige of the University of Medicine and Pharmacy from Iași, of the Society of Physicians and Naturalists and of its famous *Journal.* The documentary and affective testimonies reveal the impact he exerted on his contemporaries, colleagues and coworkers. A man like him is rarely born, to fill with the kindness of his heart the souls of those he helped, regardless of their social and intellectual position, and with the light of his mind the minds of those who were lucky enough to have him as a teacher, mentor and role model.

NEWS

ORBITAL RECONSTRUCTION USING MODERN TEHNOLOGY BASED ON 3D MODEL PRINTING

The use of digital assistance in reconstruction is increasingly used due to the advantages it implies, one of the most used technologies being the one based on stereolithography. The aim of this study is to analyze the advantages of this modern method used in the orbital fracture reconstruction. The study was performed on a group of 34 patients with unilateral orbital fractures. In order to reconstruct the orbit, a printed model was made based on stereolithography, the affected area being digitally reconstructed by mirroring of the healthy area. After that a titanium meshes were preoperatively shaped using the stereo lithic model, and then used during the reconstructive surgery. The reconstruction resulted in a satisfactory restoration of facial symmetry and good functional outcomes. Also, the duration of surgery was significantly reduced, and the precision of the reconstruction was greatly increased. This modern method based on the three-dimensional printed model used to repair the defects involving the orbit reduces the intraoperative time, making the postoperative result closer to the operator's expectations, and depending on the complexity of the case to restore the functionality of region (Blumer M, Pejicic R, Gander T, *et al*. Customized Titanium Reconstruction of Orbital Fractures Using a Mirroring Technique for Virtual Reconstruction and 3D Model Printing. *Oral Maxillofac Surg*. 2021; 79(1): 200.e1-200.e9 / doi: 10.1016/j.joms. 2020. 09.001).

ORAL HEALTH STATUS AND RELATED BEHAVIOR IN ADULTS FROM NORTH-EASTERN REGION OF ROMANIA (Abstract): Oral health represents a standard for the quality of life of the individual in a society. Good oral health allows an individual socio-economic integration as well as personal development to the maximum capacity, thus making him useful to society. The **aim** of the study was to evaluate the oral health status as well as the behavioral factors that influence this status in the adult population from the N-E region of Romania. **Material and methods**: The retrospective study data were gathered via questionnaires completed by 765 participants in the "Prophylaxis Caravan" annual event between March 2022 - April 2023. We collect demographic data, information about type of medical insurance they have, the monthly income, the type of dental office they visit, about oral hygiene habits (number of daily tooth brushings, toothbrush changing, frequency of dental check-ups) and oral health status using DMFT index and CPITN index. SPSS 26.0 was used for statistical analysis, $p<0.005$. **Results:** 64.3% of the subjects brush their teeth more than once a day, and 75.8% change their toothbrush 1-3 times/per year. 35.8% go to the dentist "when needed", 59.3% of subjects go for check-ups or treatment. DMFT = 11.4, consisting of DT= 2.38, MT=6.20 and the FT=2.49. **Conclusions**: The oral health of adults in the N-E region of Romania is influenced by an important carious experience, dental edentacy having an increased value. Health promoting behavior as well as monthly income are elements that influence the quality of oral health of the population. **Keywords**: DMFT, CPITN, ADULTS, N-E REGION OF ROMANIA.

Oral health represents a standard for the quality of life of the individual in society. Good oral health allows an individual socio-economic integration as well as personal development to the maximum capacity, thus making him useful to society. The presence of untreated oral diseases produces great pressure on society, affecting the functioning in normal parameters due to the presence of pain, discomfort, deformity, and sometimes death (1). These problems can be readily avoided if patients seek dental treatment on time. Early diagnosis of oral disorders, as well as fast clinical treatments, are promoted by good oral health-seeking behavior (2).

In Romania, even though there were socioeconomic disparities across groups, oral

health in adults has improved in recent decades. This condition can be explained by inequalities in individual oral status, as well as the impact of social variables such as economic, environmental, and lifestyle factors (3).

A low socioeconomic and education level, in association with reduced access to dental services and poor oral hygiene behavior, will result in a higher frequency and severity of dental caries and periodontal disease (4-7). The studies carried out so far in the adult population in Romania indicate an increased prevalence of oral diseases, the prevalence of dental caries varying between 70-90% (8,9) and periodontal disease between 60-70%, values that can be compared with those of neighboring countries (10).

A study on the oral health of the population in the Member States of the European Union conducted in 2010 of the percentage that in Romania, a percentage of 30% of the population declared that they are all natural. Among those who no longer have all their natural teeth, 14% are partially or totally edentulous. 32% have difficulty chewing due to dental lesions, and approximately 16% have experienced dental or periodontal pain. 16% were embarrassed by the aesthetic appearance of their teeth - the first place in Europe, while 81% believe they can reach a dentist within 30 minutes from home or work if necessary. The results of a study carried out in Iasi in 2019 regarding the level of knowledge and skills regarding oral health, showed that 35% of the participants chose toothpaste with a whitening effect, and almost 25% considered the type of toothpaste teeth rather insignificant (11).

The socioeconomic and cultural factors associated with the level of knowledge and attitudes accumulated regarding oral health have an impact on oral status. Thus, the aim of the study was to evaluate the oral health status as well as the behavioral factors that influence this status in the adult population from the N-E region of Romania.

MATERIAL AND METHODS

After receiving clearance from the Ethics Committee of the University of Medicine and Pharmacy "Grigore T. Popa" Iasi, Romania (no.322/08.06.2023), this retrospective observational study was undertaken among adults from the N-E area of Romania. The information was gathered via questionnaires presented to participants in the "Prophylaxis Caravan" oral health screening annual event.

The following criteria were used to select participants: adults over the age of 18 from Romania's N-E region, who signed informed consent and completed the full questionnaire after receiving explanations about the study under the condition of anonymity. We utilized the calculation procedure with a confidence level of p = 95% to an adult population of 3.7 million people (12), and the sample size was 385 adults (13). Because adults completed 765 of the total surveys completed at the previous activity, we chose all questionnaires completed by adults between March 2022-April 2023.

In addition to demographic questions (age, gender, residence, occupation), the questionnaire included questions about the type of medical insurance they have, their monthly income, the type of dental office they visit, and questions about oral hygiene habits (number of daily tooth brushings, toothbrush changing, frequency of dental check-ups.

The DMFT index was used to evaluate the oral health status, measured by adding

the number of decaying (DT) teeth, the number of missing (MT) teeth, and the number of filled (FT) teeth (D) (14).

To evaluate the periodontal status, we used the Community Periodontal Index of Treatment Needs (CPITN) as a method of screening that evaluates the presence or absence of periodontal pockets, calculus, and gingival bleeding. Scores from 0 to 4 are given for each tooth examined, and finally, the need for periodontal treatment is established according to the score obtained on each sextant (15).

SPSS Software Version 26.0 (*SPSS*® Inc., Chicago, IL, USA) was used to produce descriptive statistics and evaluate the data gathered. Frequency, percentages, averages, and standard deviations were used to show descriptive data. The most essential characteristics that can define person's attitudes about oral health are age, gender, occupation, monthly income, and the frequency of visits to the dentist. To assess the differences between variables, t Student test was utilized. A multivariate regression analysis was performed to assess the predisposition for an affected oral health condition. A p-value of 0.05 or less was judged statistically significant.

RESULTS

First table shows the analysis results regarding the study group's demographic data. Thus, of the total of 765 participants, 53.7% are female subjects, 81.6% come from the urban zone and 55% are unemployed (student, unemployed, retired). The average age was 47.68±17.42 years (min. 19 - max. 82 years) (tab. I).

Regarding the distribution by socio-economic 31.9% of participants have a high level, 49.7% a medium level, and 18.4% a low level. From a financial point of view, 63.5% of the participants have a monthly income > 501 €, and 64.2% are self-financed, followed by 35.8% of those who have state insurance. 78.8% of the participants frequent private clinics (tab. I).

TABLE I.

Distribution (%) of subjects according to sociodemographic (N= 765).

		No.	%
Age	47.68±17.42 (min.19, max.82)		
Sex	Female	411	53.7
	Male	354	46.3
Residence	Urban	624	81.6
	Rural	252	18.4
Occupation	Employee	344	45
	Unemployed (student, unemployed, retired)	421	55
Socio-economic level	High level	244	31.9
	Medium level	380	49.7
	Low level	141	18.4
Monthly income	EUR <500	279	36.5
	EUR >501	486	63.5
Payment for dental services	State insurance	274	35.8
	Private insurance and self-funded	491	64.2
Preferred dental clinic	Private clinic	603	78.8
	State clinic	162	21.2

The evaluated oral health habits indicate that 64.3% of the subjects brush their teeth more than once a day, and 75.8% change their toothbrush 1-3 times/per year. Regarding the number of visits to the dentist, 35.8% go to the dentist "when needed" and 34.1% "once a year". The reasons to visit a dentist were for 59.3% of check-ups or treatment and for 40.7% for dental emergencies (tab. II).

TABLE II.
Oral health habits

		No.	%
Oral hygiene habits			
Number of brushing/days	1 toothbrushing /day	273	35.7
	>1 toothbrushing /day	492	64.3
Number of toothbrushes/years	1-3 times/year	580	75.8
	>3 times/year	185	24.2
Number of visits to the dentist/ year	Less than 1 year	43	5.6
	Once a year	261	34.1
	Once in 5 years	187	24.4
	When needed	274	35.8
Reasons to visit a dentist	Check-up or treatment	454	59.3
	Emergency	311	40.7

The evaluation of the dental status achieved by determining the DMFT index indicates an important carious experience, DMFT having an average value of 11.4, consisting of DT (decayed teeth)= 2.38, MT(missing teeth)=6.20 and the FT (filled teeth) component=2.49. The increased value of the extracted teeth component is observed. In relation to certain socio-demographic variables, dental status is more affected in the case of male subjects (DMFT=12.16), in those with a low socio-economic level (DMFT=15.65), and in those unemployed (DMFT=12.68). The recorded differences were statistically significant for all evaluated variables (p=0.000) (tab. III).

In the case of the periodontal status evaluated through the CPITN index, the evaluation indicates an increased frequency of subjects presenting dental calculus, followed by those with superficial pockets (up to 5mm deep) and those with gingival bleeding. The distribution of the results in relation to the socio-demographic variables shows that male subjects (25.7%), with a high socioeconomic level (26.6%), employed (31.1%) show increased values for the dental calculus, while female subjects (16.8%), with medium socio-economic level (16.1%), unemployed (21.9%) show increased values for superficial periodontal pockets. The recorded differences were statistically significant (p=0.000) (tab. III).

Certain sanogenic habits as well as income can influence the adult's oral status. Thus, those who brush their teeth once a day have higher DMFT values (13.67) compared to those who brush more than once a day, the difference being statistically significant (p=0.000). The same trend is recorded in the case of those who go to the doctor "when needed" (toothache) (12.42) but also in those who go to the doctor only once a year (11.82). Although monthly incomes >501 euros/month, the value of

the DMFT index was higher (11.64) compared to the value recorded in the case of those with incomes < 500 euros/month (9.99) (tab. IV).

TABLE III.

Oral health status *vs.* gender, socioeconomic level and occupation

	Mean value	Gender		Socio-economic level			Occupation	
		Female	Male	High level	Medium level	Low level	Employee	Unemployed

*t student test, **ANOVA test, statistically significant differences when p<0.05

TABLE IV.

Factors related to oral health habits and dental service's frequency of utilization

	Odontal status				***P***
	DT	MT	FT	DMFT	
Number of brushings/day					
1 toothbrush /day	3.07	7.89	2.79	13.67	0.000
> 1 toothbrush/day	1.99	5.26	2.32	9.58	
Number of visits to the dentist/ year					
less than once a year	3.30	4.28	2.33	9.91	0.000
once a year	2.65	6.46	2.71	11.82	
twice a year	1.71	3.57	2.89	8.17	
when needed	2.42	8.05	2.03	12.42	
Monthly income					
< 500 euro	1.52	6.76	1.72	9.99	0.000
> 501 euro	2.87	5.88	2.93	11.64	

ANOVA test, Statistically significant differences when p<0.05

TABLE V.

Multivariate regression between gender, occupation, monthly income (independent variables), and dependent dental status and hygiene attitudes.

	B	Std. Error	Sig.	OR	95% Confidence Interval for Exp(B)	
					Lower Bound	Upper Bound
DMFT >10	.869	.215	.000			
[Gender=Male]	-.492	.161	.002	.611	.446	.838
[Occupation=employed]	-.759	.179	.000	.468	.329	.665
[Socio-economic level=high]	-.994	.238	.000	.370	.232	.590
[Socio-economic level=medium]	-.863	.208	.000	.422	.281	.635
[Monthly income=<500 euro]	-.634	.183	.001	.531	.371	.759

The multivariate logistic regression (table 5) shows us that in the case of the number of tooth brushings, male subjects have a 0.611 greater predisposition to have a DMFT>10 than female subjects (p = 0.002, OR = 0.611), the same positive trend being recorded and in the case of those employed (p = 0.000, OR = 0.468), those with high socio-economic level (p = 0.000, OR = 0.370) and medium (p = 0.000, OR = 0.422) as well as for those with monthly income <500 euros (p=0.001, OR=0.531).

DISCUSSION

Oral health, which has become a serious public health issue in every country, regardless of the degree of development, is an indication of individuals' standard of life and education (16-18). Socioeconomic and cultural factors impact the oral health of Romanians, who, despite the assistance of the medical insurance system and an increased number of dentists, have poor oral health (19-23).

The aim of our study was to evaluate the oral health status and the behavioral factors that influence this status in a group of adult patients from the N-E region of Romania. For this purpose, we analyzed the indicators of the oral status (dental, periodontal) and the behavioral factors that affect attitudes related to oral hygiene, visits to the dentist, reasons for going to the doctor or monthly income, factors that influence access to medical services

The analysis of the collected data showed us that more than half of the subjects brush their teeth more than once a day, change their toothbrush 1-3 times/per year and less than half of participants go to the dentist "when needed" or "once a year". The reasons to visit a dentist were for 59.3% of check-ups or treatment and for 40.7% of dental emergencies. This kind of behavior can explain the high carious experience, with a DMFT index having an average value of 11.4. The increased value of the extracted teeth component is observed. The dental status is more affected in the case of male subjects, those with a low socio-economic level, and unemployed. The mean DMF index in this study was

higher than in other previously studies (24-28).

In the case of the periodontal state, as measured by the CPITN index, the results show an increased incidence of participants with dental calculus, followed by those with superficial pockets (up to 5mm deep) and gingival bleeding. The distribution of the results in relation to socio-demographic variables reveals that male subjects with a high socioeconomic level who are employed have higher values for dental calculus, whereas female subjects with a medium socioeconomic level who are unemployed have higher values for superficial periodontal pockets. These findings vary from those of other research in which female respondents have superior periodontal health due to higher levels of dental care knowledge and attitudes (29, 30).

Certain sanogenic habits, as well as income level, can influence the adult's oral status (31-33). In our study those who brush their teeth once a day have higher DMFT values (13.67) compared to those who brush more than once a day. The same trend is recorded in the case of those who go to the doctor "when needed" (toothache) (12.42) but also in those who go to the doctor only once a year (11.82). The results are like those of the studies carried out so far (34-36).

The income level is linked to oral diseases and a poor quality of life in terms of oral health (38, 39). In our study, although monthly incomes >501 euros/month, the value of the DMFT index was higher (11.64) compared to the value recorded in the case of those with incomes <500 euros/month (9.99). The studies carried out so far support the fact that socioeconomic factors might impact dental service use. In Romania, dental treatments are generally supplied in private dentist offices, and patients pay for treatment out of their own pockets and access to these services is influenced by many factors (40).

Inequalities in access to medical services are found in all countries of the world, the pattern is similar in all European countries. Improving access to medical services can be done through better education regarding oral health as well as financial support for dental treatments, with the stimulation of preventive attitudes related to oral health. Currently, the costs for oral health care amount to significant values because patients in Romania present themselves to the doctor at an advanced stage of the disease, which entails high treatment costs (41, 42).

CONCLUSIONS

The results of our study show us that the oral health of adults in the N-E region of Romania is influenced by an important carious experience, dental edentulism having an increased value. Sanogenic behavior as well as monthly income are elements that influence the quality of oral health of the population.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

IN SILICO SCREENING OF SOME OLD DRUG FOR NEW APPROACHES IN HEART FAILURE (Abstract): **Aim**: The aim of the present study is to discover new approaches for old drugs, targeting heart failure (HF), using *in silico* studies. **Material and methods**: Several old drugs, belong different chemical and therapeutical classes: oral hypoglycemic drugs (sulfonylurea), proton pump inhibitors, nonsteroidal anti-inflammatory drugs, statins, H_1/H_2 antagonists, antineoplastic drugs, alfa-adrenergic agonists, vitamins and antioxidants, were tested for affinity to glycogen synthase kinase 3 beta (GSK-3β), using *in silico* molecular docking studies. Indirubin-3'-monoxime (I3M) and adenylyl-imidodiphosphate (AMP-PNP), were used as GSK-3β reference inhibitors. Moreover, the drugs with the best docking score for GSK-3β, were included in an ADME-Tox study to predict their pharmacokinetic profile. **Results:** The used computational method was validated using RSMD variation (less than 2 Å) recorded for GSK-3β inhibitors (I3M and AMP-PNP). The results showed that the binding of drugs to GSK-3β involve direct hydrogen bonds and van der Waals interactions with key amino acids from active site, Lys85, Asp133, Val135, Glu137, Arg141, Gln185, Asp200 and Arg220. **Conclusions**: Based on *in silico* results, in term of affinity for GSK-3β and ADME Tox profile, several drugs have theoretical premises to have beneficial effects in HF and could be propose for repurposing approach, which look of finding new clinical indications for existing drugs. **Keywords**: IN SILICO, HEART FAILURE, OLD DRUG, GSK-3β, REPURPOSING.

Heart failure (HF), a final common pathway of many cardiovascular diseases, develops when the heart is no longer able to provide adequate blood flow/pressure in response to the body's needs. This in turn induces the activation of several compensatory mechanisms, initially beneficial, which over time contribute to disease progression. These compensatory mechanisms include salt and water retention by the kidneys, activation of neurohormones, and triggering intracellular signaling cascades in the heart and vasculature, resulting in alterations of the cellular and organ morphology and function, with myocardial loss, left ventricular hypertrophy, or a combination of both (4). HF is characterized by severe morbidity and mortality, increasingly prevalence, poor

quality of life, and a high burden on health care systems in terms of resource use and expenditures (10). With an alarming statistic of more than 64 million people worldwide (19) suffering from HF, this syndrome is a major and growing public health problem worldwide.

In 2019, The Heart Failure Association Atlas survey observed that the median incidence of HF in Europe was 3.20 cases per 1000 person/year, ranging from ≤2 in Italy and Denmark to >6 in Germany; the prevalence was even more variable, ranging from ≤12 in Greece and Spain to >30 in Lithuania and Germany (6, 13). In the USA, the estimated 2020 prevalence of HF was 6.9 million which is expected to increase by 24% to nearly 8.5 million in 2030 (19). In Romania, approximately 4.7% of individuals aged 35 and older are affected by HF, which translates to a total of around 560.000 patients (9).

Despite significant improvement in the current therapies, patients with advanced HF have very few options other than cardiac transplantation. This is firstly due to extremely limited regenerative potential of the adult mammalian hearts. Due to this poor regenerative capacity, the injured heart has no alternate to adapt and compensate (adverse ventricular remodeling) to maintain the pump function for the time being (7). Unfortunately, adverse remodeling leads to a significantly scarred hearts, which will fail over the time. The proliferation of pre-existing cardiomyocytes (CMs) represents the primary mechanism to promote the cardiac regeneration (16). Therefore, strategies to stimulate the proliferation of pre-existing CMs are the most cited approaches to repair the injured heart. To achieve this, the research has focused towards identifying the growth factors and signaling pathways capable of enhance endogenous cardiac regenerative potential. It was identified several key pathways to take back the CMs proliferative capacity, which include (i) inhibition of Hippo pathway, (ii) direct activation of cell cycle regulators, (iii) activation of Neuregulin (NRG)-1/ErbB signaling, and (iv) inhibition of glycogen synthase kinase (GSK)-3 signaling (20).

GSK-3 is a widely distributed serine/threonine kinase initially recognized for its role in controlling glycogen synthase activity and maintaining glucose balance. It exerts control over various cellular functions, including cell growth, metabolic processes, programmed cell death, and embryonic development (17). The GSK-3 family consists of two isoforms, namely GSK-3α and GSK-3β. These isoforms have been demonstrated to exhibit both overlapping functions and isoform-specific unique roles in maintaining organ homeostasis and contributing to the development of various diseases (18). Several recent studies have highlighted the cardioprotective properties of various GSK-3β inhibitors in counteracting myocardial injury induced by hypoxia-reperfusion. Additionally, phosphorylation of GSK-3β has shown promising effects in alleviating myocardial damage caused by myocardial hypertrophy, cardiac fibrosis, cardiomyopathy, and parasympathetic dysfunction (15). Furthermore, Lin et al. explored the potential of lansoprazole (a proton pump inhibitor) in protecting against cardiac hypertrophy and HF, the fundamental mechanism involving the deactivation of the Akt/GSK-3β/β-catenin pathway, which effectively attenuated cardiac remodeling (8)

Discovery of new drugs is a very slow process, time consuming, very expensive and often it fail in best results, and related to these aspects the finding new ways to successfully convert novel ideas into day-to-day practice is crucial to improve healthcare. The new cited strategy consists in *drug repurposing*, which is a strategy used to discover new

applications for existing drugs (2).

The aim of this paper is to discover new approaches for old/existing drugs for HF, using *in silico* molecular docking studies, targeting the affinity of the drugs to GSK-3β enzyme. Moreover, the drugs with the best docking score for GSK-3β, were included in an ADME-Tox study to predict their pharmacokinetic profile.

MATERIAL AND METHODS

In silico GSK-3β docking study

For this research it was used AutoDock-GPU software, which enables fast calculations with the AutoDock4.2.6 scoring function and which facilitates the docking of very large libraries of molecules, as well as modeling of molecules of increasing size and complexity (7, 12). A large library of conventional drugs, which are currently not use for treatment of HF, was screening in terms of affinity for GSK-3β, as follow: (i) oral hypoglycemic drugs (sulfonylureas), (ii) proton pump inhibitors; (iii) nonsteroidal anti-inflammatory drugs (NSAIDs); (iv) statins; (v) H_1/H_2 antagonists; (vi) antineoplastic drugs; (vii) alfa-adrenergic agonists; (viii) vitamins; (ix) antioxidants. The results, expressed as Gibbs free energies values (ΔG), were compared to indirubin-3'-monoxime (I3M) and adenylyl-imidodiphosphate (AMP-PNP), used as reference GSK-3β inhibitors.

Generate the receptor coordinate file (RCF)

X-ray crystallographic structure of the GSK-3β was selected in terms of the quality of the model obtained from RCSB Protein Data Bank and was processed prior to docking (7). From downloaded experimental structures, was removed the ligands, the water molecules, cofactors and ions that should not be included in the receptor by a text editor. After that, each receptor was converted to PDBQT format file using AutoDock4.2.6 by reading the coordinates, adding charges, merging nonpolar hydrogens and assigning appropriate atom types.

Generate the ligand coordinate file (LCF)

Dimensional structures of the tested drugs were sketched in ChemDraw and after that were converted to PDB coordinate files using Chimera 1.14. Each LCF contain special keywords recognized by AutoDock4.2.6 like ROOT, ENDROOT, BRANCH, and ENDBRANCH that establish a rigid set of atoms and rotatable groups of atoms that are connected to the rigid root. As well, TORSDOF was used in estimating the change in free energy caused by the loss of torsional degrees of freedom upon binding. Each structure was energy minimized and converted to PDBQT format file. To study the interaction between a single ligand with a single receptor, with explicit calculation of affinity maps, a docking method was used. The receptors were kept rigid, and the ligands were allowed to be flexible (12).

Preparing the Grid Parameter File (GPF)

The GPF specifies the parameters for generating the atomic affinity maps and the PDBQT files for the receptor. For GSK-3β complex was used a grid box of 95×86×81 points with a spacing of 0.375 Å between grid points and the grid box center was put on x = 19.614, y = 11.232 and z = −6.299. The binding site of GSK-3β ligands was identified by using protein visualization software such as PyMOL, Chimera 1.14 and DSvisualizer.

Preparing the docking parameter file (DPF)

The DPF consist of which grid map files to use, which ligand molecule to dock, what is its center and number of torsions, which docking algorithm to use and how many runs

to do. For conformation search, the Lamarckian Genetic Algorithm (LGA) was applied, with the following parameters: number of runs for each docking procedure (200), number of individuals in the population (300), the maximum number of 27,000 generations simulated during each LGA run, the maximum number of evaluations at 25,000,000, a mutation rate of 0.02 and a cross over rate of 0.80, while the remaining docking parameters were set to default (7). After performing molecular docking simulation of the selected ligand molecules against the GSK-3β, the best ligand molecules were evaluated on the basis of their score against the GSK-3β receptor. All the results obtained by molecular docking simulation were evaluated on the basis of hydrophilic and lipophilic interactions obtained between the binding residues present in the active ligand binding site of the macromolecule and ligand. The dockings experiments were clustered with a root mean square deviation (RMSD) of 0.5 Å and evaluated by PyMol software.

In silico ADME-Tox study

ADME-Tox (Absorption, Distribution, Metabolism, Excretion and Toxicity) study offers important data to predict the pharmacokinetic properties and toxicity degree of new candidates, during the drug discovery process (5). The ADME-Tox profile of the tested compound was predicted using *pkCSM-pharmacokinetics* (http://structure.bioc.cam.ac.uk/pkcsm) and *SwissADME* (http://www.swissadme.ch) tools. *SwissADME* provide an overall assessment of the pharmacokinetics profile of small molecules by most relevant computational methods (14) and *pkCSM-pharmacokinetics* is a new method based on graph signatures and experimental data (11). The methods have been selected for robustness, but also for ease of interpretation to enable efficient translation to medicinal chemistry. For these *in silico* tools, the methods design description, the methods validation information and the datasets used, are provided in the literature.

RESULTS AND DISCUSION

In silico GSK-3β docking results

To predict the binding mode of the tested drugs with the GSK-3β, an X-ray crystallographic structure was selected in term of the quality of the atomic model obtained from the crystallographic data. The PDB 1J1B file was selected to study the predicted binding mode of the ligands with GSK-3β enzyme. GSK-3β was described as the kinase structure with the highest resolution to date, 1.80 Å, which means that there is a more confidence in the location of atoms in the electron density map. Furthermore, the reliability factor (R-value) was less 0.25, indicating a strong agreement between the crystallographic model and the experimental X-ray diffraction data.

The used computational method was validated using RSMD variation (less than 2 Å) for I3M and AMP-PNP, based on their affinity to the active site of GSK-3β, and it was found the same binding cleft residues reported in literature (12). Moreover, the docking results showed that both reference inhibitors have polar interactions with the catalytic site of GSK-3β, bounding deeply by specific interaction with Lys85, Asp133 and Val135. According to reported data (7), the residues Lys85, Asp133, Val135, Glu137, Arg141, Gln185, Asp200 and Arg220 are key amino acids for interactions with the binding pocket of GSK-3β.

In order to calculate the Gibbs free energies (ΔG) of tested drugs, each ligand-receptor complex was subjected to careful analysis for ideal docked position, based on the least binding energy scores and maxi-

mum number of cluster conformations, and the results are presented in first table.

The analysis of the results revealed that the estimated free binding energy of the reference GSK-3β inhibitors was less than -7 kcal/mol (AMP-PNP -8.2 kcal/mol, and I3M -7.34 kcal/mol). Based on these values, it can appreciate that compounds which obtained lowest docking score need more less energy to stabilize the compound at the ligand binding center of GSK-3β receptor and have theoretical premises to be more potent inhibitors than references. The analysis of the results revealed that there are several GSK-3β inhibitors, belong different chemical structures and therapeutic classes, more potent than references, such as: (i) sulfonylureas (oral hypoglycemic drugs): gliquidone (-11.78 kcal/mol), glimepiride (-10.25 kcal/mol), glibenclamide (-9.72 kcal/mol), glipizide (-9.41 kcal/mol), gliclazide (-8.22 kcal/mol); (ii) statins (cholesterol-lowering drugs): atorvastatin (-9.67 kcal/mol), simvastatin (-9.48 kcal/mol), fluvastatin (-9.12 kcal/mol), lovastatin (-9.08 kcal/mol), rosuvastatin (-7.88 kcal/mol); antioxidants (polyphenolic compounds): rutin (-9.41 kcal/mol), curcumin (-8.92 kcal/mol), resveratrol (-7.43 kcal/mol); vitamins: vitamin E (-8.89 kcal/mol), riboflavin (-7.59 kcal/mol); NSAIDs: indomethacin (-8.68 kcal/mol), ketoprofen (-7.77 kcal/mol); proton pump inhibitors: omeprazole (-8.47 kcal/mol), rabeprazole (-8.33 kcal/mol), lansoprazole (-7.82 kcal/mol).

Referring to the binding mode of tested drug to GSK-3β it was observed that all compounds interact by direct hydrogen bonds and van der Waals interactions with amino acids from active site. For example, the binding of gliquidone in the cleft formed between the N– and C– terminal lobes of GSK-3β, is based on interactions of sulfonylurea moiety with Asn64, Lys183, Gln185, Asn186 and Asp200 and of 1,3-dioxo-2-isoquinolinyl moiety with Arg141 *via* hydrogen bonds (fig. 1).

TABLE I.

The Gibbs free energies (ΔG) for GSK-3β of tested drugs compared to the values recorded for AMP-PNP, I3M, as GSK-3β inhibitors

Ligand	GSK-3β ΔG (kcal/mol)	Ligand	GSK-3β ΔG (kcal/mol)

***In silico* ADME-Tox results**

For ADME-Tox evaluation were selected the drugs with the best docking score. The distribution properties, based on the blood brain barrier (BBB) permeability, the volume of distribution (VDss) and the fraction unbound in plasma protein descriptors were predicted and the results are summarized in second table.

For tested drugs, the calculated values of VDss ranged from -1.918 to 1.663 and of fraction unbound ranged from 0 to 0.676. It is know that only the unbound fraction of the drug is active whereas the high binding to proteins can affect both the pharmacokinetic and pharmacodynamic profile of drugs (14, 15). In order to establish the statistical significance of the difference between the VDss and fraction unbound while removing ligand variances from the overall error variance, a two-way ANOVA analysis was applied. The results established there is no statistically significant difference between the two parameters ($F(0.5, 1, 38) = 17.202$, $p = 0.001$, Fcrit = 4.098). So, the lower VDss values are in agreement with lower value for the fraction of drug molecules in the plasma which is unbound (free) to proteins.

The BBB permeability is assessed using

two parameters, one qualitative (BBB) and other one quantitative (logBB). Depending on the BBB parameter value, the drugs are classified as drugs with high and low permeability, respectively. More specific, a logBB value higher 0.3 means that drug readily cross the BBB while a value less than −1, indicates a reduced permeability for this barrier (54). The BBB permeability values of tested drugs were predicted to range from -0.876 to −1.899 which means that are poorly distributed to the brain.

The drugs which have the best volume of distribution (VDss<0.5) and poorly blood brain barrier permeability (BBB<−1) belong from different chemical classes, such as: (i) benzimidazoles (proton pump inhibitors): lansoprazole (VDss = -1.944, BBB = -0.162); (ii) sulfonylureas (oral hypoglycemic drugs): glibenclamide (VDss = -1.918, BBB = -1.162), glipizide (VDss = -1.228, BBB = -0.908), gliclazide (VDss = -0.667, BBB = 0.108); (iii) polyphenolic compounds (antioxidants): demethoxycurcumin (VDss = -1.633, BBB = -0.563); resveratrol (VDss = -0.974, BBB = -0.961); (iv) 1,3-thiazolidines (oral hypoglycemic drugs): rosiglitazone (VDss = -1.347, BBB = -1.671); (v) cyanopyrrolidine (oral hypoglycemic drugs): saxagliptin (VDss = -1.013, BBB = 0.245). The values recorded for GSK-3β references inhibitors were VDss = -1.605, BBB = 0.236 (I3M) and VDss = 0.284, BBB = -0.912 (AMP-PNP), respectively.

TABLE II.

Distribution profile of tested drugs, predicted using pkCSM-pharmacokinetics and SwissADME tools

Ligand	VDss (human)	Fraction unbound (human)	BBB permeability	CNS permeability

CONCLUSIONS

The repurposing or repositioning of existing drugs is a new drug discovery strategy, which gaining increasing interest over the traditional de novo drug discovery, because is faster and less expensive than the last one. Using AutoDock-GPU software, which enables fast calculations with the AutoDock4.2.6 scoring function, more than 60 existing drugs, from several chemical and therapeutic classes, were assessed for their affinity to GSK-3β, as new approach in HF management. The most promising drugs, in term of affinity to GSK-3β, expressed as Gibbs free energy (ΔG), are gliquidone, glimepiride (antidiabetic drugs), simvastatine, atorvastatine (cholesterol-lowering drugs), curcumin (a powerful antioxidant) and indomethacin (an important NSAIDs). For these drugs, the value recorded for ΔG ranged between -11.78 kcal/mol (gliquidone) and -8.68 kcal/mol (indomethacin), much better than the values recorded for GSK-3β reference inhibitors, AMP-PNP (-8.2 kcal/mol), and I3M (-7.34 kcal/mol). These drugs showed also a good predictable pharmacokinetic profile, having best volume of distribution (VDss<0.5) and poorly blood brain barrier permeability (BBB<−1). The most favorable drugs will be included in large study, based on *in vitro* and *in vivo* assays, in order to prove the *in-silico* results.

CONFLICT OF INTEREST. Authors declare that there is no conflict of interest.

THE DEVELOPMENT OF ALGINATE-BASED MATRICES LOADED WITH RIFAMPICIN FOR WOUND HEALING (Abstract): The proposed study aims to develop polymeric systems based on alginate and N-vinylcaprolactam (NVCL) coated with poly(D,L-lactide-co-glycolide) (PLGA) as vehicles for Rifampicin (RIF) as active substance. Rifampicin is an agent used for tuberculosis treatment, but the present study proposes to be used for wound healing. The proposed topic is a complex study comprising a lot of data; herein information on Rifampicin loaded matrix and its antimicrobial activity against the main strains of the following bacteria: *S. aureus*, *MRSA*, *E. coli*, *P. aeruginosa*. **Materials and methods**: Alginate and NVCL were used as main materials for polymer preparation then coated with PLGA; the polymeric matrix was loaded with Rifampicin as active substance. The preparation of polymer consisted of various steps such as polymerization technique, water in oil in water emulsification and then matrix lyophilization for characterization in solid state. Chromatography was used to indicate the presence of the drug (TLC) and then HPLC was used to quantify the amount of it. The antimicrobial activity was tested by culturing the tested substances against some bacteria e.g. *S. aureus*, *MRSA*, *E. coli*, *P. aeruginosa*. **Results:** The tested matrix showed positive results in terms of drug loading and antimicrobial activity and will be further investigated for IC50 and cytotoxicity. **Conclusions**: Based on the obtained results, the proposed rifampicin-loaded alginate-based matrix shows potential in wound treatment, including surgical wound care. **Keywords**: RIFAMPICIN, ALGINATE MATRICES LOADED, WOUND HEALING.

Advancements in medical technology have led to improvements in patient care, compliance, and outcomes. Significant strides have been made in the development of materials used during or after surgical procedures. These procedures typically

involve incisions with specialized instruments in an operating theatre, often requiring anesthesia and/or respiratory support. Surgical materials, including adhesives, sealants, hemostatic agents, wound covers, absorptive sponges, and sutures, are now expected to meet specific criteria. They should be non-toxic, biocompatible, and supportive of cellular proliferation for tissue regeneration, while also possessing sufficient mechanical and physical properties for durability. Naturally sourced biopolymers, which are biological macromolecules metabolized within the body, have gained recognition for their compatibility with the biological environment. Unlike synthetic polymers, they typically do not provoke chronic inflammatory or immunological reactions or toxicity due to their similarity to the extracellular matrix. Furthermore, modifying the structure or processing conditions of biopolymers can enhance their functionality, physical-mechanical properties, regenerative capabilities, adsorptive properties, and more. Biopolymers, which are naturally occurring polymers, are typically produced by living organisms and can be sourced from microbial systems, extracted from plants, or synthesized chemically from basic biological systems. They offer several advantages over synthetic polymers, including a well-defined and more intricate structure, biocompatibility, functionality, degradability, and renewability. However, they also have drawbacks such as poor mechanical properties, lower producibility, and a dependence on various environmental factors. Nonetheless, with appropriate functionalization, their properties can be significantly enhanced. The most utilized biopolymers in surgical materials include chitosan, alginate, hyaluronic acid as polysaccharides, collagen, gelatine, fibroin as proteins, and biocompatible polymers like polylactic acid derivatives. In the subsequent section, we will outline the general properties of these key biopolymers and their roles in surgical applications. Alginic acid, a polysaccharide extracted from brown seaweeds, possesses distinct physical properties that make it valuable as a rheology modifier in various applications such as food products, paper consumables, printing inks, and biomaterials for medical and pharmaceutical preparations. Its biocompatibility and biodegradability have sparked significant research interest. Like chitosan, alginates are copolymers comprised of repeating units of guluronic acid (G) and β-D-mannuronic acid (M), linked via 1,4 glycosidic bonds. In molecular terms, they are C5 epimers of each other. The orientation of the carboxyl group (–COOH) on the C5 carbon of the six-membered saccharide ring is above the plane of the ring in the M unit and below the plane in the G unit. The polymer chain of alginate contains blocks of guluronic acid, mannuronic acid, and alternating sequences thereof. The viscosity and gel-forming capacities are key characteristics of alginate, heavily influenced by the block structure and chain length.

Among the polymers exhibiting a Lower Critical Solution Temperature (LCST) close to physiological conditions (32-34°C) are poly(N-vinylcaprolactam) and poly(N-isopropylacrylamide), rendering them suitable for biomedical applications. Poly(N-vinylcaprolactam) (PNVCL) is a water-soluble, non-toxic, thermosensitive, and biocompatible polymer categorized under N-vinylamide polymers. In comparison, although poly(N-isopropylacrylamide) (PNIPAAm) is extensively studied as a thermosensitive polymer, PNVCL exhibits even higher biocompatibility due to the

direct linkage of the amide group to the hydrophobic backbone chain (C–C). Consequently, the hydrolysis of the amide group in PNVCL does not yield small amide compounds, which are undesirable for biomedical applications and limit the biocompatibility of PNIPAAm (1, 2, 3).

The combination with biocompatible monomers such as N-vinylcaprolactam with alginate can lead to functional biocompatible materials which impart both the characteristics of alginate and NVCL. The present study aimed to prepare and characterize the nano/microparticles of alginate grafted from NVCL and covered with a shell of PLGA for applications like wound healing, particularly, healing after a surgical operation. Within the present study, there will be reported the loading of the selected model drug i.e. Rifampicin and the antimicrobial activity against 4 strains of bacteria such as *S. aureus*, *MRSA*, *E. coli*, *P. aeruginosa*.

MATERIALS AND METHODS

Chemicals

Alginic acid (AgA, Sigma Aldrich product) was utilized, along with N-vinylcaprolactam (NVCL), as monomer, achieved from Sigma Aldrich. The initiator system comprised ammonium persulphate (APS, Sigma Aldrich) and 50% hydrogen peroxide solution. The reaction was carried out in ultra-pure distilled water as the solvent. To create the nanoparticle suspension, a 0.5 wt.% acetic acid glacial solution was employed. Purification of the copolymer was achieved using a dialysis bag with a cut-off of 3.5 kDa. Rifampicin (RIF), 99% purity, with a molecular weight (Mw) of 822.95 g/mol sourced from S.C. Antibiotice S.A. Iasi, Romania. Poly(D,L-lactide-co-glycolide) 50:50 (PLGA), Sigma Aldrich product was used to form the Nano/microparticles. All other chemicals and reagents used in this study met analytical grade standards or exceeded them and were procured commercially.

Preparation of grafted biopolymer

The grafted biopolymer i.e. alginate grafted N-vinylcaprolactam (NVCL) was synthesized by using the free radical polymerization method in water by using as initiating systems of azobisisobutyronitrile (AIBN) under nitrogen flow within a ratio of 0.1% against the monomer (NVCL). The proposed mechanism was represented within the Fig. 1. The structure identification was assessed by FTIR spectroscopy.

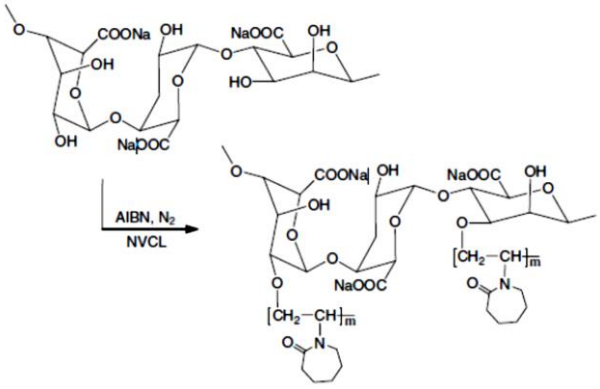

Fig. 1. The proposed mechanism for the synthesis of the polymeric matrix

Preparation of PLGA coated alginate grafted from NVCL

The prepared biopolymeric matrix was used further to synthesize nano/microparticles without and containing Rifampicin, the selected drug model for the post-surgery wound healing.

An amount of prepared biopolymer was dissolved in water within a concentration of 0.1 wt.% and then Rifampicin was added to the polymeric solution to ensure a good blending and formation of electrostatic bonds with the hydrophilic groups of the biopolymer. The theoretical amount used for the Rifampicin loading within the matrix was 0.5 wt.% against the polymer amount. The mixture was stirred for couple of hours then lyophilized.

The biopolymeric matrix without Rifampicin was dissolved in twice distilled water within a concentration of 0.1 wt.%. The oil phase solution was prepared by dissolving 0.1 g PLGA (50/50) in dichloromethane (DCM) and Span 80 was added to ensure a good stability of the emulsion. The oil phase was probe sonicated for 10 minutes then the water phase was added dropwise under strong stirring under vortex to prepare water-in oil emulsion. The first emulsion was again probe sonicated then added dropwise in the second water phase consisting of 5 wt.% polyvinyl alcohol low molecular weight, Tween 80 and salt to give the final water-in-oil-in water (W/O/W) dispersion. The solvent was evaporated at room temperature, and the system was kept under stirring overnight. The final dispersion was then centrifugated at 15000 rpm under a temperature of 5°C to collect the nano/microparticles of N-vinylcaprolactam grafted alginate (AgA-g-NVCL) coated with PLGA. The schematic representation of the procedure was illustrated within second figure.

The formation of particles containing Rifampicin was performed similarly except the fact that in the water was dissolved the matrix loaded with Rifampicin. The drug content was determined by means of high-performance liquid chromatography (HPLC).

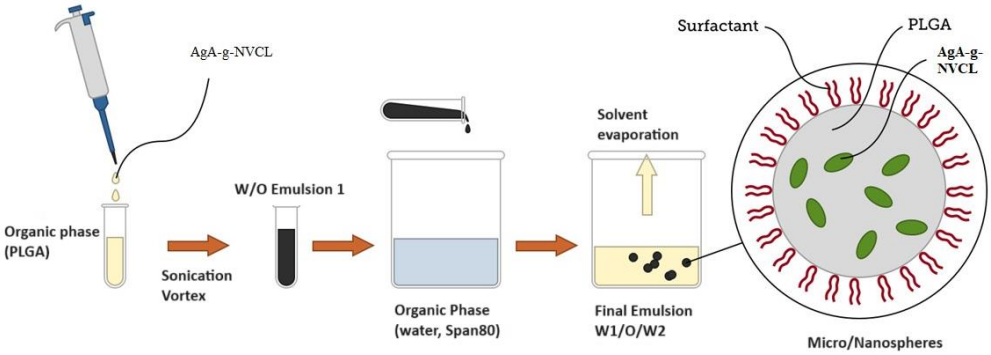

Fig. 2. Preparation scheme of Micro/Nanospheres of grafted alginate-NVCL coated with PLGA shell

Fourier transform infrared spectroscopy (FTIR) analysis

The structure was confirmed by FT-IR spectra of the copolymer films which were recorded with a Perkin-Elmer Spectrum-100 ATR-FTIR instrument by scanning in

the range of 600-4000 cm^{-1}.

Thin layer chromatographic chemical screening (TLC)

Thin Layer Chromatography (TLC) was used to separate components in the analyzed compounds. After separation, each compound shows horizontal bands at different points; each band has a specific retention factor (Rf) which be determined by using equation (1):

$$\mathbf{Rf} = \frac{\text{distance traveled by sample}}{\text{distance traveled by solvent}} \quad (1)$$

The biopolymer loaded Rifampicin was dissolved in ethanol with a concentration of 1 mg/mL. Chloroform: methanol (9:1) solvent mixture used as mobile phase to screen and determine the separation. Approximately 10 mL of mobile phase was placed into a rectangular glass tank and covered with a glass lid; the solvent-based mixtures were allowed to saturate for 10 min before use. 2 µL of each sample were placed with a capillary tube on the DC Kieselgel 60 F_{254} silica gel (0.2 mm thickness was purchased from Merck), total 5 drops. As a reference sample was used the pure drug marked as standard and placed onto silica gel as well. After separation, spots were detected at 254 nm.

HPLC method

The amount of Rifampicin was analyzed by using an Agilent 1260 high-pressure liquid chromatograph (HPLC) system. The system was equipped with UV detector and Chrompack C18 (250×4.6 mm) column, Santa Clara, CA, USA. UV detection was performed at 238 nm for Rifampicin and the HPLC conditions were applied according to the HPLC method developed by Chellini *et al.* (4). Gradient elution was carried out with a mobile phase A of 20 mM monobasic sodium phosphate buffer with 0.2% triethylamine (pH 7.0) and acetonitrile and mobile phase B was acetonitrile, at a flow rate of 1.5 mL/min. The total run time was 12 min, and the re-equilibration time was 5 min. Gradient elution was carried out as follows: 100% mobile phase A was first held for 5 min, then mobile phase B was raised up to 52% in 7 min, mobile phase B was held at this level until 12 min, and at 12.01 min, mobile phase A was switched back to 100% until 17 min (re-equilibration). The flow rate was 1.5 mL/min, and the injection volume was 25 µL. Limit of detection (LOD) and limit of quantification (LOQ) were evaluated. For the determination of Rifampicin amount, a calibration curve was done by preparing serial standard solutions within a concentration range of 0-1000 µg/mL and recorded the absorbance obtained at 238 nm, specific for RIF. For this purpose, approximately 20 mg polymeric matrix loaded with Rifampicin was weighted, then sonicated and dissolved in 250 µL CH_3OH; the solution was filtrated and 100 µL were transferred to a new vial and injected 25 µL into the chromatographic column.

Antimicrobial activity

There were used 4 bacterial strains (*S. aureus, MRSA, E. coli, P. aeruginosa*) isolated from patients with common infections. The pure and fresh culture (18 hours) of each of the 4 bacterial strains were tested against Rifampicin-loaded nanoparticles (RNPs), Rifampicin pure substance (RIF) and unloaded nanoparticles (NPs), following the Kirby-Bauer disk diffusion protocol (10^8 CFU/mL bacterial suspension, homogenous inoculation of Mueller Hinton blood

agar (5). The tested antimicrobial substances were prepared to respect the classical antibiotic discs: 6 mm in diameter. The diameter of inhibition area was measured in mm, in transmitted light, after 18-24 hours incubation at 35°C.

RESULTS AND DISCUSSION

Matrix characterization

The structure of the synthesized biopolymer was analysed by means of FTIR spectroscopy and FTIR spectrum of the prepared polymer was represented within fig. 3.

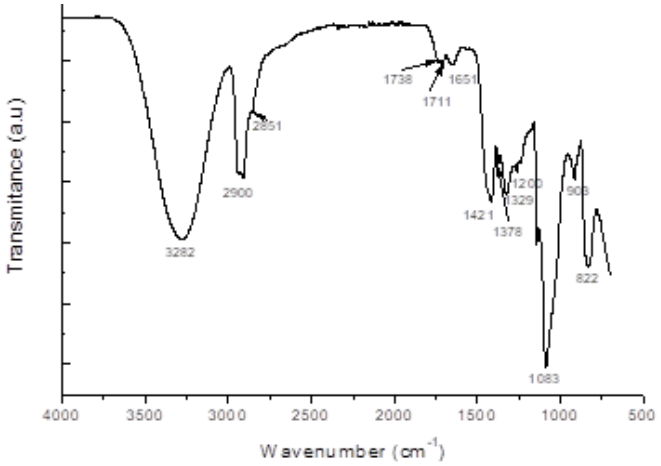

Fig. 3. FTIR spectrum of AgA-g-NVCL

During the synthesis procedure, NVCL as monomer, containing vinyl groups was polymerized and connected with alginate via ester bonds. Exploration of the FTIR spectra of the final grafted copolymer is in fact verifying whether the monomer has transformed into polymer and ensuring that the characteristic peak of vinyl groups at 1626 cm^{-1} attributed to the –C=C–stretching vibration has disappeared, showed that polymerization occurs by opening the carbon-carbon double bond without any change in the caprolactam ring. The peaks at 2926 cm^{-1} and 2856 cm^{-1} correspond to the aliphatic C–H stretching. The peak of C–N stretching vibration was observed at 1421 cm^{-1} and the peak at 3282 cm^{-1} can be assigned to N–H stretching vibrations. Similar results were found in the case of a NVCL homopolymerization, the spectrum showing similar trendline (6).

Thin layer chromatography chemical screening (TLC)

The qualitative assessment of the drug loading was performed by TLC chemical screening. The loaded sample was compared with the pure drug as standard. The Fig. 4 described the UV images recorded at 254 nm of the sample with Rifampicin and pure Rifampicin as standard. Using a silica gel plate and ethyl acetate as the development solvent, the pure drug as standards and by comparison, the loaded sample with Rifampicin showed spots having Rf's of 0.55 and 0.58, and 0.52 the latter one. Comparing these Rf polymeric matrix loaded with Rifampicin with the Rf's of standard, a similarity between the elution spots could be observed; the difference being just in the intensity due to the concentration differences.

Considering the hydrophobic character of Rifampicin, the identification of the spot belonging to the drug was facile, the results confirming the presence of Rifampicin within the polymeric matrix. Similar results were found by Abdelwahab *et al.* (7), where values of 0.44 for Rf were determined but similar trendline of elution column.

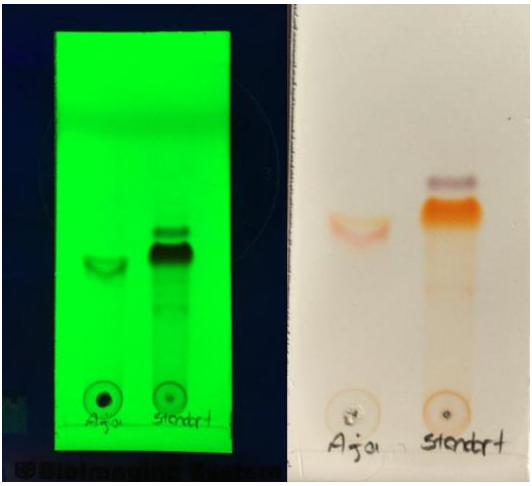

Fig. 4. The chromatographic separation of the standard substance (Rifampicin) and the loaded matrix wit Rf (left). UV images at 254 nm

HPLC method

The quantitative assessment of the drug loading was performed by HPLC analysis by using the method described with the section 2. The retention time of Rifampicin using the described method was found to be around 12.6 minutes (fig. 5).

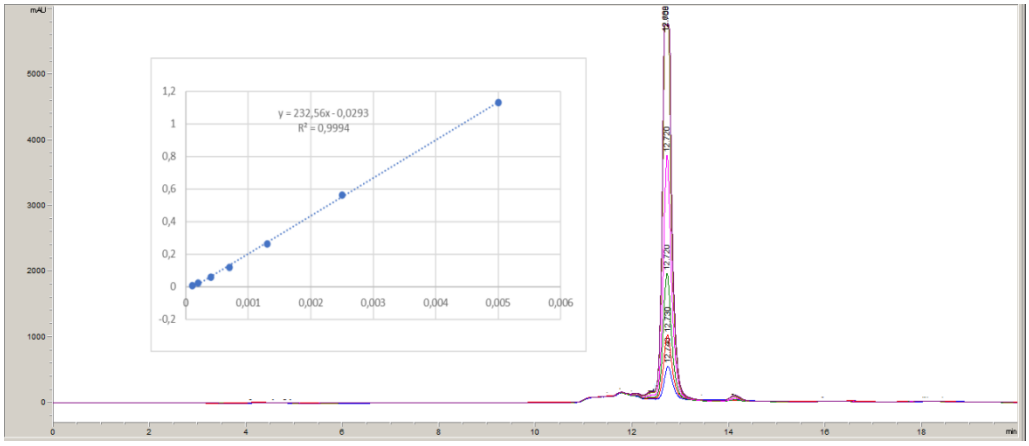

Fig. 5. Representative chromatogram of Rifampicin with its characteristic peak and the calibration curve based on HPLC analysis

The determined limit of the detection LOD and limit of quantification LOQ were found to be 0.7132 and 2.1623 µg/mL respectively. The amount of Rifampicin found in 20 mg was determined by using the calibration curve of being 160 µg/mL, a 26.66% loading as compared with the amount loaded initially. This result was considered for further studies *in vitro* (e.g. cytotoxicity, IC50 determination, etc.).

Antimicrobial activity

S. aureus, MRSA, E. coli, P. aeruginosa are bacterial strains with a high potential to produce infections difficult to be treated, if only *mecA* gene of *S. aureus* and extended-spectrum β-lactamase (ESBL)-producing *E. coli* is good to be mentioned. Other reports are mentioning the high prevalence of infected wounds with similar strains as we tested (8, 9, 10), which underline the importance of developing new therapeutical strategies. Our results are promising, but to be implemented in clinical practice we should validate our developed therapeutical drugs using the European Committee on Antimicrobial Susceptibility Testing (EUCAST) guideline (11).

The antimicrobial activity was evaluated and RNPs was found to have a good antimicrobial action against all 4 microbial strains. Fig. 6 described the images of cultured blood agar plates inoculated with *S. aureus, MRSA, E. coli, P. aeruginosa*, tested at RNPs, RIF and NPs.

The diameters of inhibition areas are summarized in first table.

As observed both from table I and figure 6, the greatest area of inhibition is against *MRSA* and comparable to those against *S. aureus* and *P. aeruginosa*. NPs have a good antimicrobial action against *MRSA* and *E. coli*, which recommends this type of matrix for its use in therapy after loading with antimicrobial substances, to which it will give added efficacy. It should be noted that on *P. aeruginosa*, neither Rifampicin has antimicrobial action and even less so NPs, which was to be expected, while RNPs have good antimicrobial action, and so they are particularly valuable for use in healing superinfected wounds or for preventing superinfection in immunocompromised patients.

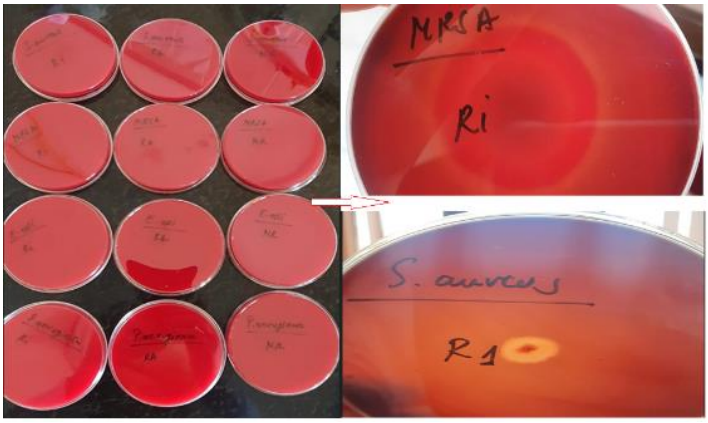

Fig. 6. Images of blood agar plates inoculated with *S. aureus, MRSA, E. coli, P. aeruginosa*, tested at RNPs, RIF and NPs

TABLE I.

The diameters of inhibition areas for the Rifampicin-loaded nanoparticles (RNPs) comparative with the Rifampicin pure substance (RIF) and the unloaded nanoparticles (NPs)

	RNPs		RIF		NPs	
	24 h	48 h	24 h	48 h	24 h	48 h
S. aureus	35	40	complete inhibition	complete inhibition	5	10
MRSA	41	45	1/2 inhibition	1/2 inhibition	15	26
E. coli	24	26	30	30	18	18
P. aeruginosa	32	36	-	-	-	-

RIF was expected to have very good efficacy, as proven on *S. aureus* (complete inhibition) and *MRSA* (1/2 inhibition), and against *E. coli*, but the side effects of high concentrations of Rifampicin are not to be neglected and therefore RNPs are a viable and highly effective alternative in the care of postoperative wounds/sores/burns in general.

In all cases the zone of inhibition increased slightly after 48 hours, which indicates maintenance of the antimicrobial activity for a long time, from which it follows that the application to the wound of the pharmaceutical form with RNPs (as ointment, dressing, patch, etc.) can be done at a long interval and will thus improve patient compliance to proper wound care.

CONCLUSIONS

The study had the purpose to prepare materials suitable for the treatment of post-surgical wounds by using Rifampicin as the active substance. The first step within this complex study was to select a proper matrix, i.e. polymeric matrix which has the role not only to protect the active substance but also to release it at the target site without creating a burst delivery. Moreover, the matrix should be biocompatible and non-toxic for the human body. Considering the data from literature a copolymer of alginic acid and N-vinylcaprolactam seemed a good choice and it was tested from the perspective of loading and matrix compatibility with Rifampicin and its antimicrobial activity against very powerful bacteria commonly found in post-surgical infections (e.g. *S. aureus*, *MRSA*, *E. coli*, *P. aeruginosa*). Rifampicin loading in the PLGA-coated alginate and PNVCL copolymer matrix was demonstrated qualitatively by TLC and quantitatively the drug loading was found to be 26.66% using the HPLC method. As regarding its antimicrobial activity, it was found out that the inhibition against the bacterial agents increased slightly even after 48 hours, indicating the persistence of the antimicrobial activity for a long time, making the systems suitable for wound healing, including post-surgical wound treatments, when this time of 48 hours is extremely important.

THE MEDIATING ROLE OF SLEEPING PROBLEMS, BURNOUT SYNDROME, STRESS, DEPRESSIVE SYMPTOMS, AND SELF-EFFICACY ON THE RELATIONSHIP BETWEEN ATTITUDES TOWARDS APPEARANCE AND BODY DISSATISFACTION AMONG ROMANIAN YOUNG PEOPLE (Abstract): The **aim** of the study was to evaluate the presence of anxiety, depression, burnout, and dissatisfaction with body image among young people in Romania. **Materials and methods:** A total of 432 respondents aged 18-30 were included in the research, and several instruments were used: SES-SQ evaluated the socioeconomic level; DASS 21 for the severity of central symptoms in the sphere of depression, anxiety, and stress; the BSQ items assessed body dissatisfaction and concern over body shape; the GLQ questionnaire identified scores related to physical activity, cognitive activities, social activities, other leisure activities, and other behaviors that significantly influence health; and the SATAQ-4 assessed socio-cultural attitudes towards appearance by measuring the pressure from peers, family, and the media to attain the ideal appearance, internalization of the thin/low body fat and internalization of the muscular or athletic body image. The statistical analyses were performed using IBM *Statistical Package for Social Sciences (SPSS) for Windows, version 24* (SPSS Inc, Chicago, IL, USA). **Results**: Sex, the presence of a chronic disease, marital and socioeconomic status was found to be important in depression, anxiety and satisfaction with the body image. Age was found to be related to some of the variables: the older the respondent was, the lower the levels of stress, depression or anxiety. Additionally, age correlates negatively with burnout and sleeping problems, in the sense that as one ages, burnout levels decrease, and sleep disturbances become less prevalent. Negative correlations were also identified between age and the pressure felt from the media. Young people with chronic diseases had a statistically significantly higher level of internalization of thin/low body fat. **Conclusions:** The results showcased a significant correlation between factors such as age, gender, marital and socio-economic status and the impact of stress, depression, anxiety on the perception of body image and related levels of dissatisfaction. **Keywords**: SLEEPING PROBLEMS, BURNOUT SYNDROME, STRESS, DEPRESSIVE SYMPTOMS, SELF-EFFICACY, BODY DISSATISFACTION.

INTRODUCTION

Contemporary society places significant emphasis on self-perception and the manner which body image is perceived by the social group. Numerous studies have highlighted the link between mental health and satisfaction with body image among children and adolescents, but a lack of body satisfaction is very prevalent among adolescents. While this pertains more to weight or the existence of physical abnormalities in children, it frequently involves a desire for aesthetics and group approval among adolescents and young adults; thus, we are discussing group pressure and social pressure.

Media channels and social networks reinforce this desire to have a perfect body, and virtual reality makes it easier to satisfy the desire to look the way everyone wants: selfie posts, photo editing, or video manipulation are common.

The lack of satisfaction with body image and appearance has negative consequences on the physical, mental, and social health. According to Fox *et al.* (1), girls and young women report the feeling of pressure to conform to gender and beauty norms more frequently, and they are more likely to post photos that show them as more attractive. The position of self-objectivation (seeing themselves as a third party) is associated with poor health, shame, low self-esteem, anxiety, depression, sleep-related problems, eating disorders, and low cognitive performance (2, 3). Several studies have indicated that individuals who have low body image satisfaction are more critical of themselves when they are in a negative mood (4). Furthermore, the literature does not distinguish between men and women in this regard. For example, Matias and his team (5) showed that body dissatisfaction is associated with psychological concerns among both genders, but these concerns do not represent a motivational incentive to adopt healthy behaviors. Therefore, many researchers mentioned that the psychological impact of body dissatisfaction should represent a public health concern due to its negative consequence on psychological balance and general quality of life, including sleep disorders (6), depression (7), eating disorders (8), physical exercises (9), burnout syndrome (10), and self-efficacy (11, 12). Self-efficacy is one of the most important factors related to the process of changing behaviors and adopting healthy ones, referring to the subjective prediction of one's ability to accomplish a certain task or fulfill a specific goal (13, 14).

The aim of the present study was to identify the mediating role of sleeping, burnout syndrome, stress, depressive symptoms, and self-efficacy on the relationship between attitudes towards appearance and body dissatisfaction among Romanian young people.

MATERIALS AND METHODS

Participants. The study was carried out between September and November 2023, and the questionnaires were distributed online to young people on social networks (Facebook, WhatsApp). Participants were informed about the purpose of the study, about the fact that they could withdraw from the study whenever they wanted, without consequences, and about the confidentiality of data. No incentive was given to respondents. The inclusion criteria were young people aged between 18 and 30 years old who agreed to participate in the study and filled out the questionnaire before the deadline. The exclusion criteria were incomplete questionnaires, in which the young people

did not express their consent to participate, and questionnaires filled in by people over 30 years old. After applying the inclusion and exclusion criteria, a total of 432 questionnaires were included in the research.

Data collection. The online questionnaire was developed using the Google Forms application (Alphabet, Mountain View, CA, USA), to obtain detailed information about satisfaction with body image, acceptance of dominant socio-cultural standards for appearance, as well as the influence of stress, depression, and anxiety on these variables.

The first part of the questionnaire gathered socio-demographic information, such as age, gender, marital status, living environment, educational level, the presence or absence of chronic disease diagnosis, the type of diagnosed disease (if applicable), and socioeconomic status). The body mass index (BMI) was calculated considering the weight and height declared by the participants.

Some items investigated cultural and religious characteristics and nutrition-related habits as well as physical activity, such as the frequency of consuming home-cooked meals, preference for foods that require little preparation time, frequency of dining at restaurants, the importance of consuming locally-produced food, the adherence to religious fasting, the consumption of food supplements or slimming teas, as well as performing physical exercises to maintain body shape. Additionally, a few items investigated the respondents' availability to accept minimally invasive aesthetic procedures or aesthetic surgeries to beautify or change the facial appearance, as well as the use of photo editors or filters when displaying photos on various social networks (e.g, Facebook, Instagram etc.).

Socioeconomic characteristics were evaluated using SES-SQ developed by Roohafza *et al*. (15). The SES-SQ consisted of six items. As the authors sustained, the evaluation of socioeconomic status is a major predictor of health and nutritional status as well as mortality and morbidity related to many diseases.

The next part of the questionnaire included the following psychological instruments:

- DASS 21 - is a set of three self-assessment scales built to assess negative emotional states and the severity of central symptoms in the spheres of depression, anxiety, and stress (16). The reliability of DASS-21 showed that it has excellent Cronbach's alpha values of 0.81, 0.89, and 0.78 for the subscales of depression, anxiety, and stress, respectively;

- sections from the Copenhagen Psychosocial Questionnaire (COPSOQ) related to individual health and well-being, which includes several factors: 1 – self-assessed health, 2 – sleep disorders, 3 – burnout, 4 – stress, 5 – somatic stress, 6 – cognitive stress, 7 – depressive symptoms, 8 – self-efficacy (17);

- The BSQ 16-item is a refined self-report questionnaire developed by Evans and Dolan (18) to assess body dissatisfaction and concern over body shape. Participants rate the items based on a six-point Likert scale, ranging from 1 = *never* to 6 = *always* with higher scores indicating greater body shape dissatisfaction. This instrument has been found to be a reliable and valid measure of body image satisfaction as it has demonstrated excellent internal consistency (0.95);

- SATAQ-4 is a 22-item questionnaire assessing socio-cultural attitudes towards appearance, measuring media, family, and

peer pressure to attain the ideal appearance; internalization of the thin/low body fat; internalization of the muscular or athletic body image. SATAQ-4 subscale scores demonstrated good internal consistency (0.84 or higher) (19);

- The General Lifestyle Questionnaire (GLQ) questionnaire (20) which includes five subscales related to physical activity, cognitive activities (attention, memory and reasoning), social activities, other leisure activities (including activities that we practice mainly for relaxation or personal enrichment, for example, meditation) and other behaviors that significantly influence health (eating habits, alcohol consumption, tobacco consumption, and sleep quality). GLQ scores are calculated using a 5-point Likert scale (score 1 = never, 2 = several times in the last year, 3 = several times a month, 4 = several times a week, 5 = every day or almost every day). Overall, Cronbach's alpha coefficients were satisfactory, with an overall Cronbach's alpha score of 0.72.

Statistical analysis

The statistical analyses were performed using IBM Statistical Package for Social Sciences for Windows, *SPSS version 24* (SPSS Inc, Chicago, IL, USA). The results for descriptive statistics were expressed as means (M) and standard deviations (SD). The normality of the data distribution was tested using the Kolmogorov-Smirnoff test. Given the fact that all data are normally distributed, parametric tests will be applied. To assess comparative results considering gender, living environment, and the presence or absence of chronic diseases, the Independent T Test was performed. Comparative results considering marital status, weight status, and socio-economic status were assessed using the ANOVA One Way Test to determine if there were statistically significant differences between more than two groups of an independent variable or a quantitative dependent variable. The Pearson correlation was used to test the relationship between variables. A p-value < 0.05 was considered statistically significant.

RESULTS

The average age of the participants was M = 20.71 ± 2.60 years old, with most of them being women (81.7%, N = 353). About half of the participants were single (48.8%, N = 211), less than half of them were in a relationship (46.5%, N = 201), and the fewest were married (4.6%, N = 20).

The participants of the study had a medium level of education, with most of them having high school education (83.3%, N = 360), and a very small part of them having completed university studies (11.3%, N = 49). Additionally, most of the participants reported having an average financial situation (76.6%, N = 331).

The SES-SQ instrument, which measures socio economic status, showed that more than half of the participants had a medium economic level (55.1%, N = 238), and more than a third had a high economic level (39.9%, N = 172). The score of SES-SQ ranged from 3 (0.5%, N = 2) to 17 (2.1%, N = 9), with the average of the participants being M = 11.61 ± 2.76. As indicators of health status, weight and the presence of chronic disease were considered. More than half of the participants were of normal weight (63.2%, N = 273), while more than a quarter were either underweight (15.7%, N = 73) or overweight (16.9%, N = 68). The smallest proportion of the participants were obese (4.3%, N = 18).

Although most of the participants did not suffer from chronic diseases (92.1%, N = 398), among those diagnosed with such a disease (7.9%, N = 34), most suffered from gastrointestinal diseases (1.6%, N = 7), autoimmune diseases (1.4%, N = 6), diabetes (1.2%, N = 5), skin diseases (0.7%, N = 3) etc.

Most of the participants reported consuming home-cooked food daily (74.1%, N = 320), while more than a quarter of them at eat a restaurant once every 2-3 months (36.6%, N = 158) or 2-3 times a month (34.7%, N = 150). About half of the participants preferred to buy fresh ingredients for cooking over frozen options quite often (48.8%, N = 211). Less than half of the participants opted for food from local producers or farmers' markets instead of supermarkets quite rarely (41.9%, N = 181). More than a third of the participants occasionally (38.0%, N = 164) or frequently (35.0%, N = 151) consumed traditionally prepared preserved foods such as mashed vegetables, pickles and jam.

More than half of the participants stated that they did not resort to various food diets to lose weight (60.9%, N = 263), or consumed various weight-loss teas or food supplements (86.3%, N = 373). Less than a quarter of the participants occasionally (24.1%, N = 104) or rarely (22.0%, N = 95) engaged in excessive exercise for weight loss or body shape maintenance. Over half of the participants (69.0%, N = 298) reported not utilizing various photo filters or photo editors for the pictures they post on various social media platforms. Other items are detailed below, (tab. I), where the answers were indicated on a Likert scale ranging from 1 (total disagreement) to 5 (total agreement).

TABLE I.
Self-rated items[1]

Items	1	2	3	4	5	M±SD
I buy fresh ingredients for cooking (e.g, meat, vegetables, etc.) to cook over frozen options.	1, (0.2)	39, (9.0)	91, (21.1)	211, (48.8)	90, (20.8)	3.81 ± 0.87
I buy food from local producers or farmers' markets rather than from supermarkets.	16, (3.7)	126, (29.2)	181, (41.9)	91, (21.1)	18, (4.2)	2.93 ± 0.90
It is important to me that the food I eat is prepared the way my family cooked it.	91, (2.1)	27, (6.3)	180, (41.7)	167, (38.7)	49, (11.3)	3.51 ± 0.85
I prefer foods that are prepared quickly rather than those that take more time to cook.	15, (3.5)	61, (14.1)	203, (47.0)	121, (28.0)	32, (7.4)	3.22 ± 0.90
I eat canned food, traditionally prepared by myself or family members.	6, (1.4)	61, (14.1)	164, (38.0)	151, (35.0)	50, (11.6)	3.41 ± 0.91
It is important to me that the food I eat comes from my own country.	31, (7.2)	69, (16.0)	208, (48.1)	84, (19.4)	40, (9.3)	3.08 ± 1.00
I read food labels.	11, (2.5)	77, (17.8)	145, (33.6)	132, (30.6)	67, (15.5)	3.39 ± 1.02
Since abiding by religious fasts is important to me, my eating behavior undergoes important changes during these periods.	120, (27.8)	83, (19.2)	129, (29.9)	68, (15.7)	32, (7.4)	2.56 ± 1.25

[1]Means and standard deviations (M±D), frequency and percentages (%)

Approximately half of the participants reported a good state of health (46.5%, N = 201), with an average evaluation of health of M = 7.68 ± 1.56 on the Likert scale ranging from 1 (very bad) to 10 (very good).

The DASS-21 demonstrated strong reliability in our study, with Cronbach's alpha values of 0.87, 0.87, and 0.85 for the stress (M = 18.50 ± 9.02), depression (M = 13.10 ± 8.58) and anxiety (M = 15.56 ± 9.27) subscales, respectively.

The interpretation of these subscale values can be found in second table.

TABLE II.
DASS Severity Classification[1]

	Normal	Mild	Moderate	Severe	Extremely severe
Stress	163 (37.7)	78 (18.1)	86 (19.9)	73 (16.9)	32 (7.4)
Depression	146 (33.8)	89 (20.6)	120 (27.8)	43 (10.0)	34 (7.9)
Anxiety	91 (21.1)	23 (5.3)	107 (24.8)	69 (16.0)	142 (32.9)

[1]Frequency and percentages (%)

An independent-samples t-test was run to determine if there were significant differences between women and men on this scale. The results showed that men (M = 15.11 ± 8.52) reported lower stress levels than women (M = 19.26 ± 8.97, $t(430)$ = -3.754, $p <$ 0.001. Moreover, men (M = 11.84 ± 8.00) reported lower levels of anxiety than women (M = 16.39 ± 9.22); $t(430)$ = -4.004, $p <$ 0.001.

This study found that people living in rural areas had statistically significantly higher levels of anxiety (M = 14.15 ± 8.00) compared to people residing in urban areas (12.45 ± 8.87), t(430) = 2.016, p= 0.044. There was a statistically significant difference between groups in terms of marital status as determined by the one-way ANOVA ($F(2,429)$ = 7.313, p = 0.001). A Tukey post hoc test revealed that married people (M = 11.50 ± 8.82) had a statistically significantly lower level of stress compared to single people (M = 19.39 ± 9.18), p = 0.001 and people who were in a relationship (M = 18.27 ± 8.59), p = 0,004.

A one-way ANOVA was performed to compare the level of depression on marital status and revealed that there was a statistically significant difference in marital between the three groups (F(2, 429) = 10.053, $p<$ 0.001). Tukey's HSD Test found that married people (M = 6.40 ± 7.85) had statistically significantly lower level of depression compared to single people (M = 14.48 ± 9.24), $p<$ 0.001 and to people who were in a relationship (M = 15.21 ± 8.30), p = 0,008. Additionally, results showed that single people (M = 14.48 ± 9.24) had statistically higher levels of depression compared to people who were in a relationship (M = 12.32 ± 7.48), p = 0,029. A one-way ANOVA was also performed to compare the level of anxiety on marital status and it revealed that there was a statistically significant difference in marital status between the two groups (F(2, 429) = 4.263, p = 0.015). Results showed that single people (M = 16.38 ± 9.93) had a statistically higher level of anxiety compared to married participants (M = 10.30 ± 9.78), p = 0,015.

There was a statistically significant difference between groups in terms of socioeconomic status as determined by the one-way ANOVA ($F(2,429)$ = 5.128, p = 0.006). A Tukey post hoc test revealed that people with a middle socioeconomic status (M = 19.73 ± 9.37) had a statistically significantly higher level of stress compared to people with a high socioeconomic status (M = 16.87 ± 8.46), p = 0.005. A one-way

ANOVA was also performed to compare the level of depression with socioeconomic status and revealed that there was a statistically significant difference ($F(2, 429) = 5.155$, $p = 0.006$). Results showed that people with a middle socioeconomic status ($M = 14.11 \pm 8.81$) had a statistically significantly higher level of depression compared to people with a high socio-economic status ($M = 11.50 \pm 8.13$), $p = 0.007$.

A one-way ANOVA was performed to compare the level of anxiety on socioeconomic status and revealed that there was a statistically significant difference ($F(2, 429) = 6.597$, $p = 0.002$). Tukey's HSD Test found that people with a high socioeconomic status ($M = 13.59 \pm 8.50$) had a statistically significantly lower level of anxiety compared to people with a middle socioeconomic status ($M = 16.86 \pm 9.60$), $p = 0.001$.

The **COPSOQ wellbeing scales** consisted of several items collected with a five-point Likert scale (categories ranging from "never" to "always"). The single items of the COPSOQ scales were transformed to a theoretical range from 0 (representing the lowest possible value of the aspect under investigation) to 100 (representing the highest possible value). Scale values are presented as mean values. Cronbach's Alpha was employed to evaluate the internal consistency of the scales, demonstrating good reliability: 0.74 for sleep disorders, 0.85 for burnout, 0.79 for general stress, 0.74 for somatic stress, 0.85 for cognitive stress, 0.85 for depressive symptoms, and 0.84 for general self-efficacy. Table III presents the results according to gender, for the seven COPSOQ wellbeing subscales.

TABLE III.
Gender differences for COPSOQ wellbeing subscales.[1]

Subscales	Men	Women	Differences
Sleep disorders	36.15 ± 17.55	39.53 ± 19.57	p = 0.158
Burnout	50.07 ± 25.14	56.92 ± 21.02	p = 0.012
General stress	43.45 ± 21.99	48.44 + 21.05	p = 0.060
Somatic stress	25.31 ± 20.67	33.76 ± 18.47	p = 0.000
Cognitive stress	38.44 ± 20.80	43.89 ± 22.03	p = 0.046
Depressive symptoms	42.32 ± 25.88	45.57 ± 22.16	p = 0.255
General self-efficacy	72.46 ± 18.49	65.21 ± 17.86	p = 0.001

[1] Means and standard deviations (M±D), frequency and percentages (%)

An independent-samples t-test was run to determine if there were significant differences between people living in urban areas and those living in rural areas on the COPSOQ scale. The results showed that people who lived in urban areas ($M = 37.17 \pm 19.86$) reported lower levels of sleeping troubles than people who lived in rural areas ($M = 41.71 \pm 17.91$). This difference was significant: $t(430) = 2.401$, $p = 0.017$. Additionally, the results showed that people living in urban areas ($M = 30.16 \pm 19.25$) reported lower levels of somatic stress than people living in rural areas ($M = 35.50 \pm 18.57$) , $t(430) = 2.839$, $p = 0.005$.

The results of the research showed that people diagnosed with chronic diseases had statistically a significantly higher level of burnout ($M = 63.41 \pm 17.95$) compared to people who did not have such a diagnostic

(55.00 ± 22.17) , t(430) = 2.152 , p= 0.032.

There was a statistically significant difference between groups in terms of marital status, as determined by the one-way ANOVA (F(2,429) = 5.759, p = 0.003). A Tukey post hoc test revealed that single people (M = 58.26 ± 21.46) had a statistically significantly higher level of burnout compared to married people (M = 42.18 ± 22.56), p = 0.005. Cronbach's Alpha score for the BSQ scale was 0.94. The overall BSQ score averaged at M = 43.43 ± 19.20, with scores ranging from 16 (0.7%, N = 3) to 96 (0.2%, N = 1). An independent-samples t-test was conducted to determine if there were significant differences between women and men on this scale. The results showed that men (M = 34.18 ± 14.05) reported a lower level of body dissatisfaction compared to women (M = 45.50 ± 19.60). This difference was significant t(430) = -5.972, p < 0.001.

This study found that people diagnosed with chronic diseases had a statistically significantly higher level of body dissatisfaction (M = 51.76 ± 18.62) compared to people who did not have such a diagnostic (42.72 ± 19.11) , t(430) = 2.653, p= 0.008.

A one-way ANOVA was performed to compare the level of body dissatisfaction on weight status and revealed that there were statistically significant differences in the three groups (F(3, 428) = 20.080, p< 0.001). Tukey's HSD Test found that normal-weight people (M = 42.85 ± 18.51) had a statistically significantly higher level of body dissatisfaction compared to underweight people (M = 32.62 ± 10.98), p< 0.001. Results showed that normal-weight people (M = 42.85 ± 18.51) had a lower level of body dissatisfaction compared to overweight people (M = 50.52 ± 20.96), p = 0.007. Additionally, results showed that overweight people (M = 50.52 ± 20.96) had a lower level of body dissatisfaction compared to underweight participants (M = 64.11 ± 19.37), p = 0,026.

For the **SATAQ scale**, Cronbach Alpha was 0.91 for total scale, 0.85 for Internalization (thin/low body fat) 0.87 for Internalization (Muscular or Athletic), 0.95 for Pressures-Media, 0.87 for Pressures-Family and 0.89 for Pressures-Peers. For SATAQ subscales we obtained the following results:

TABLE IV.

Gender differences for SATAQ scale and subscales.[1]

Subscales	Men	Women	Differences
Internalization Thin / Low Body Fat	12.49 ± 4.42	14.89 ± 5.39	p = 0.000
Internalization Muscular / Athletic	16.41 ± 5.00	13.44 ± 4.68	p = 0.000
Pressure Media	8.12 ± 4.88	11.24 + 5.49	p = 0.000
Pressure Family	8.22 ± 3.77	8.19 ± 4.38	p = 0.956
Pressure Peers	7.70 ± 3.62	7.32 ± 4.05	p = 0.440
General SATAQ score	52.97 ± 13.99	55.11 ± 17.13	p = 0.302

[1] Means and standard deviations (M±D), frequency and percentages (%)

This study found that people diagnosed with chronic diseases had statistically significantly higher levels of internalization of thin/low body fat (M = 16.88 ± 4.41) compared to people who did not have such a diagnostic (14.25 ± 5.33), t(430) = 2.796 , p= 0.005. Moreover, results showed that people diagnosed with chronic diseases had

statistically significantly higher levels of socio-cultural pressures from media (M = 13.50 ± 4.82) compared to people who did not have such a diagnostic (10.43 ± 5.50), t(430) = 3.145, *p*= 0.002.A one-way ANOVA was conducted to compare SATAQ subscale levels among different marital status groups, uncovering statistically significant differences in the internalization of thin, low body fat levels (F(2, 429) = 3.835, p = 0.022). The Tukey's HSD Test found that single people (M = 14.82 ± 5.28) had a statistically significantly higher level of internalization of the thin, low body fat compared to married people (M = 12.90 ± 5.95), *p* = 0.041. Additionally, one-way ANOVA results for the pressure from the media subscale (F(2, 429) = 5.470, *p* = 0.005) showed that married people (M = 6.85 ± 3.68) had a lower level of *socio-cultural* pressure from the media compared to single people (M = 11.07 ± 5.58), *p* = 0,003.

A one-way ANOVA was performed to compare the level of internalization of the thin/low body fat on socioeconomic status and revealed that there was a statistically significant difference (F(2, 429) = 4.930, *p* = 0.008). Tukey's HSD Test found that people with a high socioeconomic status (M = 14.85 ± 4.86) had a statistically significantly higher level of internalization of the thin, low body fat compared to people with a middle socioeconomic status (M = 13.34 ± 4.79), *p* = 0.001. For the present study, the Cronbach Alpha score was 0.77. **General lifestyle scores,** as measured with the GLQ, ranged from 94 up to 190 (M = 143.83 ± 15.14). The following results were obtained for GLQ subscales: *physical activity*- M = 28.40 ± 6.84, *cognitive activities* - M = 18.72 ± 6.16, *social activities*- M = 32.53 ± 3.97, *other leisure activities* – M = 23.64 ± 3.56, *eating habits, alcohol consumption, tobacco consumption, and sleep quality* - M = 36.39 ± 4.86.

A one-way ANOVA was performed to compare the levels of GLQ subscales on marital status, and revealed that there were statistically significant differences in terms of physical activity levels (F(2, 429) = 5.066, *p* = 0.007). The Tukey's HSD Test found that single people (M = 29.43 ± 7.08) had a statistically significantly higher level of physical activity compared to people who were in a relationship (M = 27.55 ± 6.55, *p* = 0.015).

A one-way ANOVA was performed to compare the levels of GLQ scale and subscales on socioeconomic status. There was a statistically significant difference (F(2, 429) = 5.751, *p* = 0.003) on GLQ scale. Tukey's HSD Test found that people with high socioeconomic status (M = 146.72 ± 15.49) had a better overall lifestyle compared to people with middle socioeconomic status (M = 142.17 ± 14.96), *p* = 0.008. There was a statistically significant difference between groups on GLQ subscale measuring social activities (F(2, 429) = 16.599, *p*< 0.001). The Tukey's HSD Test demonstrated that people with high socioeconomic status (M = 33.67 ± 4.00) participated in more social activities compared to people with low socioeconomic status (M = 29.59 ± 3.73), *p*< 0.001 and to people with a middle socioeconomic status (M = 31.97 ± 3.72), *p* <0.001. Furthermore, results found that people with a low socioeconomic status (M = 29.59 ± 3.73) engaged in fewer social activities compared to people with a middle socioeconomic status (M = 31.97 ± 3.72), *p*= 0.017.

There was a statistically significant difference between groups in terms of weight status and *Sleep, diet and consumption subscale* as determined by the one-way

ANOVA ($F(3,428) = 3.860$, $p = 0.010$). A Tukey post hoc test revealed that underweight people (M = 37.81 ± 4.79) had a statistically significantly higher level on this scale compared to overweight people (M = 35.22 ± 4.93), $p = 0.008$.

The correlational analysis showed that there were significant associations between the participants' age and certain variables. We identified that the older the age, the higher the BMI (r = 0.121*, p = 0.012). The results showed that age correlated negatively with stress (r = -0.186**, p < 0.001), depression (r = -0.115*, p = 0.016), and anxiety (r = -0.204**, p < 0.001) in the sense that the older the age, the lower the levels of stress, depression, or anxiety. Furthermore, age correlated negatively with burnout (r = -0.196**, p < 0.001) and sleeping problems (r = -0.179**, p < 0.001) variables in the sense that the older the age, the lower the levels of burnout, and fewer problems with sleep appear. Negative correlations were identified between age and the pressure felt from the media (r = -0.104*, p = 0.031), in the sense that the older the age, the lower the level of *socio-cultural* pressure from the media. Moreover, age correlated negatively with social activity (r = -0.099*, p = 0.039), in the sense that the older the people get, the fewer social activities they perform.

The Pearson correlation results showed that there were positive correlations between BMI and the BSQ total score (r = 0.396**, p < 0.001), in the sense that the higher the BMI, the higher the body dissatisfaction.

The results showed that BMI correlated with SATAQ subscales such as Internalization of body fat (r = 0.204**, p < 0.001), Pressure from Media (r = 0.163*, p = 0.001) Pressure from Family (r = 0.441**, p < 0.001)and Pressure from Peers (r = 0.355**, p < 0.001), in the sense that the higher the BMI, the higher the internalization of a thin, low body fat, and the more *socio-cultural* pressures from the media, family, or peers were felt. Furthermore, there were negative correlations between BMI and the GLQ total score (r = -0.101*, p = 0.036), in the sense that the higher the BMI, the less healthy the lifestyle of the participants.

The correlational analysis showed that there was a positive correlation between socioeconomic status and the GLQ total score (r = 0.188*, p < 0.001), in the sense that the higher the socioeconomic status, the healthier the lifestyle of the participants. The results showed that socioeconomic negatively correlated with cognitive stress (r = -0.160**, p = 0.001), somatic stress (r = -0.187**, p < 0.001), burnout (r = -0.149**, p = 0.002), sleeping problems (r = -0.102*, p = 0.034), anxiety (r = -0.161**, p = 0.001) and depression (r = -0.169**, p < 0.001) in the sense that the higher the socioeconomic status, the lower the participants' levels of cognitive stress, somatic stress, burnout, depression, anxiety, and the fewer sleep problems appear. Other correlational results are presented in Table V.

A multiple regression was run to predict body dissatisfaction from depression, anxiety, and stress. This resulted in a significant model, $F(3, 248) = 27.309$, $p < 0.001$, $R2 = 0.161$. Further analysis of the individual predictors revealed that depression ($t = 3.075$, $p = 0.002$) and anxiety ($t = 2.435$, $p = 0.015$) were significant predictors but stress was not ($t = 0.584$, $p = 0.559$). Another multiple regression was run to predict *socio-cultural* attitudes towards appearance from sleeping problems, burnout, depressive symptoms,

self-efficacy, somatic stress, and cognitive stress. This resulted in a significant model, $F(6, 425) = 9.373$, $p < 0.001$, $R2 = 0.342$. Further analysis of the individual predictors revealed that depressive symptoms ($t = -4.313$, $p < 0.001$) and self-efficacy ($t = -1.885$, $p = 0.006$) were significant predictors but, sleeping problems ($t = 0.444$, $p = 0.657$), burnout ($t = -0.564$, $p = 0.573$), somatic stress ($t = 1.336$, $p = 0.182$), and cognitive stress ($t = -0.928$, $p = 0.354$) were not.

* p < 0.05; ** p < 0.001.

The study assessed the *mediating role of sleeping problems, burnout, general stress, cognitive stress, somatic stress, depressive symptoms, and self-efficacy on the relationship between attitudes towards appearance and body dissatisfaction*. The results revealed a significant indirect effect of impact of attitudes towards appearance on body dissatisfaction through sleeping problems(b = 0.832, t = 3.783, p = 0.002), burnout (b = 1.018, t = 4.067, p = 0.001), general stress (b = 0.629, t = 3.440, p = 0.006), somatic stress (b= 0.950, t = 4.363, p < 0.001), cognitive stress (b = 1.058, t = 4.250, p < 0.001), depressive symptoms (b = 1.779, t = 7.071, p < 0.001), and general self-efficacy (b = -1.262, t = -4.060, p < 0.001).

The study also found a significant indirect effect of the impact of body dissatisfaction on attitudes towards appearance through sleeping problems (b= -0.093, t = -2.335, p = 0.002), somatic stress (b= 0.043, t = 2.258, p = 0.002), depressive symptoms (b= 1.731, t = 3.404, p = 0.007), and general self-efficacy (b= -0.079, t = -2.330, p = 0.021). Furthermore, the direct effect of

attitudes towards appearance on body dissatisfaction in the presence of the mediators was also found to be significant ($b = 0.730$, $p < 0.001$). Hence, sleeping problems, somatic stress, depressive symptoms, and general self-efficacy partially mediated the relationship between attitudes towards appearance and body dissatisfaction.

DISCUSSION

The present research showed that sex, age, marital status, socioeconomic level, the presence of a chronic disease, and BMI are important variables. The analysis of the data revealed that men were less stressed and anxious, and they were less likely to have body dissatisfaction compared to women. These results are congruent with the scientific literature and can be explained by the fact that, usually, men are less accurate in evaluating their weight compared to women. Young women were more accurate in estimating their BMI, so they could be more objective in expressing dissatisfaction with their body weight. Additionally, failing to estimate overweight could generate a low level of involvement in dieting or the practice of healthy behaviors (21-23). Dye and his team (24) also showed in their study that women reported higher preoccupation with weight, dieting, and eating restraint than men.

Age. The research showed that the older the respondent was, the lower the levels of stress, depression, or anxiety. Additionally, age correlated negatively with burnout and sleeping problems. Negative correlations were identified between age and the pressure felt from the media and social activity, in the sense that the older the people got, the fewer social activities they performed, and the less pressure from the media they felt. Some other authors maintain that age plays a significant role in the relationship between body dissatisfaction and BMI. This is because BMI increases across the transition from adolescence to young adulthood. The studies of Bucchianeri *et al.* (25) and Bully *et al.* (26) identified opposite results regarding the fact that youth become increasingly dissatisfied with their bodies. The first research team identified that young females were more dissatisfied with their body image, while Bully and his team found that there were not important differences throughout the years.

Marital status was found to be an important factor, the study revealing that married people presented statistically significantly lower levels of stress, depression, anxiety, and burnout syndrome compared to single people or those in a relationship. The results of the research identified that married respondents presented a lower level of *socio-cultural* pressure from the media and a lower level of internalization of the thin, low body fat compared to single subjects. Single people had a statistically significantly higher level of physical activity compared to people who were in a relationship.

Rosenqvist *et al.* (27) identified that in case of married women, satisfaction with body image is related to the level of education. These differences in body dissatisfaction based on educational level were found to be important in public health actions aiming to reduce socioeconomic inequalities in health and well-being.

Socio-economic status. There was a statistically significant difference between groups in terms of socioeconomic status. Results showed that people with a middle socioeconomic status had a statistically significantly higher level of depression, anxiety and stress compared to people with

a high socioeconomic status. We also found that people with a high socioeconomic status had a statistically significantly higher level of internalization of the thin, low body fat compared to people with a middle socioeconomic status. Subjects with a high socioeconomic status had a better overall lifestyle and had better social activity compared to respondents with middle socioeconomic status. The data showed that the higher the socioeconomic status, the healthier the lifestyle of the participants and the lower the participants' levels of cognitive stress, somatic stress, burnout, depression, anxiety, and fewer sleep problems. Therefore, health policies prioritize addressing socioeconomic factors to ensure that individuals from all socioeconomic backgrounds have equal access to recreational, medical, psychological, and recovery health services. These policies also aim to promote changes in nutritional and physical activity behaviors that contribute to overall health, while emphasizing the importance of high-quality food.

Chronic disease. People who were chronically ill had statistically significantly higher levels of burnout syndrome, and they registered higher levels of body dissatisfaction compared to young people with no chronic disease. Young people with chronic diseases obtained statistically significantly higher levels of internalization of the thin, low body fat and a significantly higher level of *socio-cultural* pressure from the media, compared to people who did not have a diagnostic. Our results are congruent with those of the scientific literature, but this variable should also be interpreted considering the type of chronic disease. For example, Markey *et al*. (28) identified that the acceptance of pain was associated with reports of body appreciation in case of young people with chronic pain; Wabich *et al*. (29) showed that 87% of patients with inflammatory bowel disease reported body dissatisfaction; and Darukhanavala *et al*. (30) proved that the rate is about 21% among men and 66% among women with cystic fibrosis.

BMI. The analysis of the answers identified that the higher the BMI, the higher the body dissatisfaction. We found that normal-weight young people had a statistically significantly higher level of body dissatisfaction compared to underweight people, but a lower level of body dissatisfaction compared to overweight people. We also found that underweight people obtained a statistically significantly higher level on the scale *Sleep, diet and consumption* compared to overweight respondents.

In order to predict body dissatisfaction from depression, anxiety, and stress, the multiple regression showed a significant model, and indicated that depression and anxiety were significant predictors, but stress was not.

We also found that sleeping problems, somatic stress, depressive symptoms and general self-efficacy partially mediated the relationship between attitudes towards appearance and body dissatisfaction.

CONCLUSIONS

In this study, by using a specific questionnaire to collect relevant information related to socio-economic and psychological factors, we assessed the impact of sleeping problems, burnout syndrome, stress, depressive symptoms, and self-efficacy on the relationship between attitudes towards appearance and body dissatisfaction among Romanian young people. The study was conducted on people aged between 18-30 years old. The results showcased a significant correlation between

factors such as age, gender, marital and socio-economic status and the impact of stress, depression, anxiety on the perception of body image and related levels of dissatisfaction.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

THE USE OF NURSING WORK INDEX AS A PRACTICE CONDITIONS ASSESSMENT FOR THE ROMANIAN NURSE'S CASE (Abstract): The work conditions of nurses have a significant impact on the practice of nursing. Suboptimal working conditions can be attributed to insufficient workplace structure, substandard organization of tasks, inadequate training, and unsuitable staffing policies. **Materials and methods:** This research sought to analyze the factors that influence the work conditions of nurses by employing the practice conditions scale of the Nursing Work Index (NWI). The validation of the NWI was conducted, utilizing nurse-reported job features as the independent variables. A total of 746 nurses from hospitals located in North - East Region of Romania were included in the sample. The Nurse Forecasting (RN4CAST) protocol was implemented for data collection. **Results:** The NWI construct was accounted for by 42.9% through factors such as "Advancement opportunities", 'Learning opportunities', 'Satisfaction with current job', 'Professional status', and 'Level of education'. An analysis of the NWI revealed the presence of distinct variables within a five-factor structure. The mean score achieved on the Nursing Work Index was observed to be among the least favorable in comparison to earlier survey findings. **Conclusions:** It is imperative for nurses to be acknowledged as peers within the healthcare sector, thereby requiring empowerment for professional growth and access to career advancement prospects. Furthermore, the significance of inter-professional relationships and equitable participation of nurses in hospital matters cannot be understated. **Keywords**: NURSES WORK CONDITIONS, NURSE WORKFORCE, ASSESSMENT OF THE PRACTICE CONDITIONS, NURSING WORK INDEX.

The Nursing Work Index (NWI) is a widely used tool to evaluate the work conditions of nurses. Developed by Dr. Marlene Kramer and colleagues in the 1980s, it assesses the features of the nursing work conditions that contribute to satisfaction at work and the quality of patient care. The NWI helps in identifying the strengths and weaknesses within the nursing practice conditions and is instrumental in guiding improvements (1, 2).

Using this tool can be measured the several dimensions of the nursing work conditions, such as nurse participation in hospital operations, nursing fundamentals for high-quality healthcare, and nurse-physician collaboration (3, 4). Implementing the NWI involves surveying nursing

staff using a validated questionnaire. The responses are then analyzed to produce scores for each component, highlighting areas of strength and opportunities for improvement. Hospitals can then develop targeted interventions to address the identified issues.

In addition, studies (3, 4) using the NWI have consistently shown that better work conditions, as indicated by higher NWI scores, are associated with improved nurse satisfaction at work, lower burnout rates, and better patient outcomes. For example, research has demonstrated that hospitals with supportive management, adequate staffing, and good nurse-physician relationships have lower patient mortality rates and higher levels of patient satisfaction. This shows that by focusing on key areas, the NWI provides a comprehensive picture of the factors influencing nurse satisfaction and patient care quality (5, 6, 7).

Referring to applications and benefits, hospitals use the NWI for quality improvement, identifying areas needing improvement and implementing strategies for enhancing the work conditions. Also, the NWI allows for comparison across different units or hospitals, helping to benchmark performance and identify best practices. Not least, the NWI is frequently used in research to study the impact of work conditions on nurse outcomes, such as satisfaction at work, retention, and patient care quality.

The Nursing Work Index (NWI) is structured around several key components that collectively assess the quality of the nursing work conditions. Each component focuses on different aspects of the work conditions that are crucial for nurse satisfaction and effective patient care. Those key components are: *the involvement of nurses in hospital operations* (3, 6); *nursing fundamentals for high-quality healthcare* (4, 7); *capacity, support, and leadership of nurse managers* (5, 6); a*ppropriate staffing and resources* (6, 7) and *nurse-physician collaboration* (3, 6).

As additional components can be considered *Flexibility Of work schedule* (this includes the ability to balance work and personal life, which can significantly affect satisfaction at work and performance) and *professional development* (opportunities for further education and career growth are essential for maintaining a motivated and skilled nursing workforce).

Overview of research literature

As seen above, the Nursing Work Index (NWI) is a widely utilized tool in nursing research to evaluate and enhance the work conditions for nurses. The NWI's application in research studies, highlighting its impact and findings. For example, (8) suggest that NWI can be used to investigate the relationship between nurse staffing levels, nurse burnout, job dissatisfaction, and patient mortality. The study found that better nurse staffing was associated with lower patient mortality, reduced nurse burnout, and higher satisfaction at work. It emphasized the importance of adequate staffing and supportive work conditions in improving patient outcomes. Other researchers (9) used the NWI to examine the association between the nursing work conditions and patient safety outcomes, including the incidence of adverse events. The research highlighted that positive work conditions, as measured by the NWI, were linked to lower rates of adverse events and better overall patient safety. Another relevant study (10) explored the impact of the nursing work conditions on satisfaction at work, stress, and burnout among nurses

using the NWI. It was found that better work conditions significantly reduced stress and burnout, while increasing satisfaction at work among nurses. Also, (11) focused on adapting and validating the NWI for use in different cultural contexts, particularly in non-Western countries. The study confirmed that the NWI is a reliable and valid tool across various cultural settings, making it useful for international research and practice improvements.

Recent studies have continued to explore and validate the Nursing Work Index (NWI), focusing on various aspects of the nursing work conditions and its impact on nurse satisfaction and patient care quality. Thus, (12) aimed to update and revise the NWI to better reflect contemporary nursing practice. The research included a cross-sectional survey of hospital nurses to assess the relevance of the existing items and the addition of new ones. he revised instrument, PES-v2021, included several new items and removed outdated ones. The study confirmed that the revised scale is valid and reliable for assessing current nursing work conditions. (13) re-validated the NWI-Revised (NWI-R) in Finnish hospitals aspiring for Magnet status. It aimed to identify organizational features that influence nurse autonomy and satisfaction at work. The study found that components like nurse management and leadership, staffing and resource adequacy, and nurse-physician collaboration are crucial for a favorable nursing practice condition. The NWI-R demonstrated good internal consistency and validity. (14) evaluated the work conditions of nurses in Slovenian hospitals using the NWI, aiming to understand how job features affect nurses' perceptions of their work conditions. The study found that staffing and resource adequacy, nurse manager ability, and leadership significantly impact the perceived quality of the work conditions. The reliability of the NWI was confirmed, though some subscales showed varying levels of reliability. (15) reviewed the translation and cultural adaptation of the NWI across different countries and languages. It aimed to identify gaps and ensure the tool's applicability in diverse cultural contexts. The research identified translations into 24 languages across 35 countries, highlighting the need for further translation efforts in Africa, Asia, and South America. The study emphasized the importance of robust translation processes to maintain the tool's reliability and validity.

The purpose of our research study is to characterize and investigate the factors that influence nurses' work conditions by using the Nursing Work Index (NWI). The objectives of this research are: to analyze the regional context of nurses' work conditions in public hospitals from North-East Region of Romania using the NWI scale; and to evaluate the impact of factors that can affect nurses' self-evaluation of their work conditions, which managers can utilize to enhance nurses' working circumstances.

MATERIALS AND METHODS

Design - To get the data required to investigate areas with limited knowledge or to understand particular aspects better, a cross-sectional study was carried out. To collect the data needed was used the research protocol applied in RN4CAST (16). STROBE checklist was utilized to report the cross-sectional study.

Instrument - The NWI (2) scale was used. This scale consists of several subscales that assess different aspects of the nursing work conditions. Each subscale

includes specific items that nurses rate based on their experiences.

The first part of the scale contains 8 items that refer to respondent's socio-demographic features and professional membership: gender (0 - Male, 1 - Female), age, education level (1- Vocational health school, 2 - High school studies, 3 - Post-secondary studies, 4 - University studies, 5 - Postgraduate studies or equivalent (e.g., master programs, PhD, or advanced professional training), the department where the respondent works, whether they occupy or not a management position, and the geographic location.

The second part contains 81 items designed to assess the healthcare management dimensions and nursing practice conditions such as the involvement of decision factors; the management of human resources (selection of human resources, training of the nursing staff, the involvement of medical personnel); process management (simplifying administrative procedures for patients' admission in hospital, administrative support and clinical output, clinical outcomes of healthcare); supporting services provided by the hospital; focus on the healthcare services; focus on the employee; evaluation of indicators for hospital performance; system of hospital information; errors, safety, and risk management; the hospital organizational culture; quality management of healthcare and sustained improvement of the healthcare services, governance and social responsibility.

The third part includes 23 items related to factors that can create problems for the nurses' ability to fulfil their professional role. The list of items for each of the selected items of the Nursing Work Index is given in, Appendix.

For the items established for our questionnaire, scales were chosen to reflect the frequency of certain opinions. Thus, for the items in the first section of our questionnaire, we generally used the binomial scale and nominal scale. Since the scale with six or more points is valid and distinctive, a 7 - point Likert scale was used for the items in the second part of the proposed questionnaire (where: 1 - the lowest possible score; 2; 3; 4; . . . .7 - the highest possible score; quality), and a 10-point Likert scale was used for the items in the third part of the questionnaire (where: 1 - creates no problems at all; 2; 3; 4; ….10 - causes the most important problems).

Sample size, composition and data collection - Considering the RN4CAST protocol (16), all hospitals units form the North-East Region of Romania were asked to join in the study (N = 76). Of these, just 10 hospitals confirmed their participation. Eight regular hospitals and two larger hospitals that provide tertiary care.

All employed nurses at the included hospitals (N = 2021) were invited to take part to our study. Nurses who were absent due to illness, pregnancy leave, or holiday were excluded (N = 657). In total, 746 nurses participated to our study. Nurses are defined as those matching the European Union definition of trained and licensed nurses according to Directive 2005/36/EC (17).

The data collection period began in April and will last until June 2023. Each hospital has two weeks to collect data. The research coordinator employed a paper-and-pencil and delivered printed questionnaires. Participants submitted them in a sealed box to the agreed-upon pickup site.

Ethical considerations - Permission to conduct the study in hospitals from North-

East Region of Romania was obtained from the Hospitals Medical Ethics Committee (for example, No. 30/E3333, March 31st, 2023). All techniques were carried out in line with applicable standards and laws, including the standards for Research Ethics in the Social Sciences and Humanities (18) and the Helsinki Declaration (19). Each hospital approved its involvement by deciding on the ethics committee. Participants received written information about many parts of the study; their rights to participate voluntarily and removal from the study at any time were addressed, as were their privacy and confidentiality rights. Participants also indicated their approval of participating in the study and authorization to utilize national data for professional and scientific objectives.

Data analysis. The data underwent examination through the utilization of the statistical software *SPSS version 26*. Various forms of statistical analysis, including univariate and bivariate approaches, were conducted alongside the application of descriptive statistics and multivariate analysis. Due to the quantification of each item on a scale ranging from 1 to 7, the mean composite score for each subscale of NWI, in addition to the overall composite score, was established. The assessment of the reliability of the scales was carried out using Cronbach's alpha coefficient. Furthermore, the construct reliability of the measurable scales was evaluated through the use of Confirmatory Factor Analysis (CFA), and factor analysis. Principal Component Analysis (PCA) and Principal Axis Factor Analysis (PAF) were used to generate the most related structure of the instrument. The minimum threshold for communalities was established at 0.400. Subsequent to the identification of correlations among factors, the rotation method involving Keiser normalization was implemented. Utilization of Bartlett's test ($p < 0.05$) and KMO test (> 0.8) demonstrated adequacy of the sample size (20). A linear regression model was employed, with significance set at the p-value < 0.05.

RESULTS

Study participants

The population of nursing staff working in hospitals that participated in our study ranged from 48 to 1266. The response rate was 36.91% (n = 746), hospital response rates ranged from 20.1 to 67.2%. The lowest and highest number of responses per hospital were 49 and 264, respectively. Respondents included 654 (87.7%) females and 92 (12.3%) males.

The sample included 262 nurses with a professional health school (35.1%), 143 bachelor's degree (19.2%), 131 post-secondaries (17.6%), 193 university studies (25.9%), and 13 postgraduate studies (1.7%). The higher length of respondent's turnover was between 5 and 10 years (38.9%) and more than 10 years (36.1%). Almost all (97%) were employed full time.

Explorative results

The mean levels of satisfaction degree regarding the existing job, career, and work conditions are illustrated in (tab. I, fig.1) of the Appendix These findings provide insight into the self-evaluation outcomes concerning various job aspects. Among these aspects, the least satisfactory was the salary, followed by growth opportunities. An examination of the data revealed no apparent link between gender, educational attainment, and age in the nursing profession and the average value of the five dimensions. Conversely, a notable association was identified between the five dimen-

sions and job-related attributes. Furthermore, the established dimensions exhibited a significant relationship, as indicated in of the Appendix. The majority of these relationships fell within the medium range (r = 0.300 to 0.600).

TABLE I,
Examining job features and exploratory analysis between variables

Variables	N	M (SD)	F1	F2	F3	F4	F5

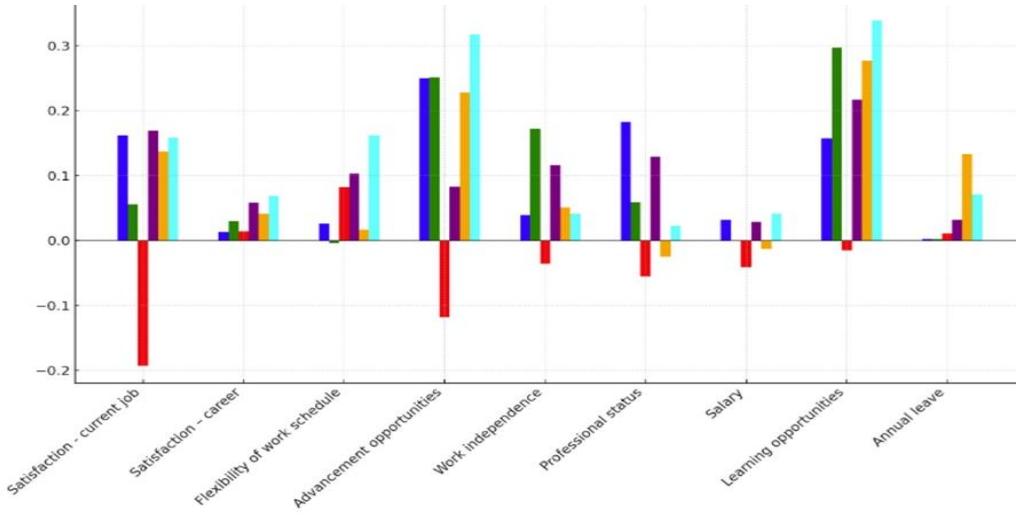

Fig. 2. The effect of job characteristic on NWI scale and developed factors.

Table II and second figure presents findings from two linear regression models. The initial model, Regression Model 1, indicates that 42.9% of the variance in the NWI scale, encompassing all items, can be accounted for. Noteworthy explanatory factors include 'Advancement opportunities', 'Satisfaction with current job', 'Learning opportunities',

and 'Professional status', with 'Level of education' being a less influential factor. In the subsequent Regression Model, Factor 1 ('Quality of management process') is associated with 41.4% of the variance, primarily explained by beta coefficients of 'Advancement opportunities' and 'Learning opportunities', followed by 'Level of education'. Factor 2 ('Challenges of nurse's professional role') is linked to 21.8% of the variance by beta coefficients such as 'Satisfaction with current job', 'Professional status', 'Advancement opportunities', and 'Learning opportunities'. Factor 3 ('Nurse manager proficiency in providing support to nurses') demonstrates an explained variance of 35.8%, with beta coefficients including 'Learning opportunities', 'Satisfaction with current job', 'Work independence', 'Advancement opportunities', and 'Flexibility 0f work schedule'. Factor 4 ('Nurses' involvement in hospital management') is connected to 32.8% of the variance, primarily through beta coefficients of 'Satisfaction with current job', 'Advancement opportunities', and 'Learning opportunities'. Lastly, Factor 5 ('Nurses development') is associated with 37.1% of the variance, primarily explained by beta coefficients of 'Satisfaction with current job', 'Advancement opportunities', and 'Learning opportunities'.

DISCUSSION

Prior studies have confirmed that the variables identified in the regression model of our research influence the work conditions of nurses. However, our study delves deeper into these variables by utilizing the NWI scale as a dependent variable. In a literature review by (21), the predictors linked to NWI are summarized, with each study highlighting only two to three significant variables related to self-assessed workplace features and their connection to NWI (such as nurse power, satisfaction at work, and organizational commitment). Another literature review involving nine studies by (22) revealed that findings regarding nursing workplace features were significant, either through composite scores or subscale scores of NWI. While some associations were significant at one analytical level, they did not hold at another level. Our study aims to showcase the intricate nature of nurse workplace features, providing valuable insights for managers in hospitals from North-East Region of Romania to enhance the work conditions for nurses.

Implications for managers

Our research delineates the workplace setting of two professional cohorts and elucidates the features of the work conditions that can serve as a valuable resource for managers to enhance the working conditions of nursing staff in North - East Region of Romania. Given the shortage of Bachelor of Science in Nursing (BSN) graduates in Romania, nursing services are delivered by a healthcare team with varying levels of educational background, necessitating vigilant monitoring of the impact of such services. As posited by (8), the substitution of registered Nurses with individuals possessing lower educational credentials heightens the potential risk for patient mortality.

The primary discovery in our research highlights that the satisfaction levels regarding wages, annual leave, and career selection do not impact the self-evaluation of the work conditions by nursing staff. According to (23), wages play a role in nurse outcomes, but the work conditions and staffing are even more significant. Our regression analysis, along with its components, indicates that opportunities for career advancement and further education are vital for survey participants, reflecting a response to obstacles in their career progression. These two factors largely accounted for the NWI scale and its respec-

tive dimensions. Subsequently, satisfaction at work elucidated two out of the three dimensions of the work conditions. (24) discovered a close relationship between satisfaction at work among hospital nurses and various factors such as the work conditions, empowerment culture, organizational commitment, professional commitment, job-induced stress, patient satisfaction, and patient-nurse ratios. Alongside the established predictors (career development opportunities and Learning opportunities), our study identifies satisfaction at work as a significant predictor influencing the work conditions of nurses.

The cultivation of collegial relationships may cultivate positive atmospheres that enhance nurse satisfaction (25). Enhancing the relationship between nurses and physicians, as well as nurses and leaders, can enhance equal engagement and the professional development of nurses in hospital administration. A similar impact was noted on the managerial skills of nurses, leadership qualities, and the support they receive. The interaction between nurses and physicians and the behavior exhibited towards nurses by physicians are critical, shaping the professional standing of nurses, providing educational prospects, and nurturing the evolution of nursing as a vocation and field, which are also deemed essential predictors in our study and others (22, 26, 27, 28, 29).

It is evident that nursing administration across various levels of healthcare facilities needs to establish a supportive condition for professional practice in order to ensure workforce stability and deliver optimal care, a notion previously acknowledged in prior studies utilizing the NWI scale (30). Enhancing the work conditions for nurses is imperative, encompassing the promotion of continuous education, advanced degrees, professional growth, and fostering a sense of camaraderie among peers (31). The creation of an ideal work setting for nurses stands as a critical responsibility for both managers and leaders. According to (28), implementing interventions aimed at enhancing the work conditions proves to be an effective strategy in enhancing satisfaction at work. Retention of nurses in their positions is encouraged through three pivotal elements: proficient leadership, opportunities for empowerment, and avenues for professional advancement (27). Equally significant is the imperative for national healthcare policies to regard nurses as equivalent healthcare professionals, recognizing nursing as both a profession and a field of science.

We acknowledge that nursing practice conditions are intricate and contextually dependent; certain aspects of the work conditions may have more pronounced impacts across different levels of analysis and contextual settings (25). Nurturing nurse empowerment, fostering engagement, and cultivating positive interpersonal relationships within the workplace are fundamental for fostering a favorable work condition and ensuring high-quality patient care (26).

CONCLUSIONS

The study suggests a decreased level of self-assessment regarding the work conditions. Some attributes of the work setting have been pinpointed as potential enhancements that hold significant value for nursing administration, hospital governance, and policymakers involved in the enhancement of nursing personnel in North-East Region of Romania. A pivotal discovery from our analysis pertains to the two factors that displayed the most substantial impact in enhancing the nursing work conditions: opportunities for career advancement and educational prospects. Emphasis should be placed on acknowledging nurses as peers within the healthcare

domain who necessitate empowerment for professional growth and access to career progression pathways. The establishment of inter-professional relationships and equitable participation of nurses in hospital operations are paramount. It is imperative for national healthcare policies to regard nurses as equivalent healthcare professionals and to recognize nursing as both a vocation and a scholarly discipline. Further longitudinal and interventional research endeavors are imperative for a more comprehensive comprehension of the working conditions of nurses.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

INSTITUTIONAL REVIEW BOARD STATEMENT

The study was conducted in accordance with the Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy Iasi (No. 128/24.11.2021) for studies involving humans.

RELATIONSHIPS BETWEEN CLINICAL MANIFESTATIONS AND HISTOPATHOLOGICAL FEATURES IN ENDOMETRIOSIS: IMPLICATIONS FOR PRECISION DIAGNOSIS AND TREATMENT (Abstract): Endometriosis is a chronic inflammatory disease affecting reproductive-age women, often associated with pain and infertility. **Aim:** This study aims seeks to investigate the relationships between clinical and paraclinical presentations, and histopathological features in endometriosis, with the objective of improving diagnostic accuracy and guiding personalized treatment strategies. **Materials and methods**: A prospective study was carried out involving 40 patients evaluated at "Cuza-Vodă" and "Elena-Doamna" Obstetrics and Gynecology Clinical Hospitals, Iasi, between September 2019 to August 2024, of whom 40 met the inclusion criteria. Key clinical data and biomarker levels, including CA-125, neutrophil-to-lymphocyte (NLR), platelet-to-lymphocyte ratios (PLR) and systemic immune inflammation index (SII) were analyzed for correlations with histopathological findings, as well as with rASRM staging and the EFI index. **Results:** Compared to the control group, the association of elevated CA-125 levels with systemic inflammatory markers (NLR, PLR, SII) highlights the chronic inflammatory process characteristic of this pathology. In terms of systemic inflammatory markers, the rASRM classification identifies lower values in stage IV compared to stage III, while the EFI classification does not reveal any significant changes. **Conclusions:** The study highlights the importance of correlating clinical and histopathological data in endometriosis for a more nuanced staging and personalized treatment approach. The association of CA-125, systemic inflammatory markers, and rASRM staging may provide the foundation for the identification of novel non-invasive biomarkers, as well as potential prognostic factors for endometriosis**.** **Keywords:** ENDOMETRIOSIS, HISTOPATHOLOGY, INFLAMMATORY MARKERS, INFERTILITY, PERSONALIZED TREATMENT.

INTRODUCTION

Endometriosis is a persistent inflammatory disorder that occurs when tissue similar to the endometrium located outside the uterus, impacting around 10% of women of reproductive age globally (1). This condition often presents with chronic pelvic pain, painful menstrual cycles (dysmenorrhea), pain during intercourse (dyspareunia), and infertility, collectively diminishing the quality of life for those affected (2). Endometriosis is increasingly recognized as a systemic condition influenced by hormonal, immune, and genetic factors (3).

The underlying causes of endometriosis remain under investigation, with several theories proposed. This encompasses the retrograde menstruation theory, proposing that menstrual blood moves back into the pelvic cavity, along with mechanisms such as coelomic metaplasia and embryonic cell migration, each offering distinct pathways for ectopic tissue formation (4, 5). In addition to physical symptoms, endometriosis has been linked to psychological and social challenges, along with comorbidities such as anxiety and depression, highlighting the importance of comprehensive management strategies (6). Endometriosis is staged in conformity with the *revised American Society for Reproductive Medicine* (rASRM) classification system, which ranks the disease from stage I to severe stage IV based on lesion size, location, and the presence of adhesions (7). Nonetheless, the relationship between ASRM staging and clinical severity - particularly in terms of pain and infertility-remains unclear, encouraging further exploration of histopathological characteristics that could elucidate differences in symptom presentation (8). Utilizing data from the rASRM classification, the EFI score can serve as a predictor of the likelihood of spontaneous pregnancy within three years postoperatively in patients with endometriosis (6).

This study seeks to delve into the interplay between clinical presentations-such as pain intensity, reproductive challenges, and other symptomatic expressions-and the histopathological features of endometriotic lesions, including tissue structure, depth, and hormonal receptor presence. By mapping these correlations, this research aims to deepen the understanding of endometriosis as a multifaceted disease, potentially enhancing diagnostic accuracy and recommended tailored therapeutic approaches that consider both the clinical profile and tissue-specific pathology of each patient.

MATERIALS AND METHODS

Sample selection

To achieve findings that reflect the demographics of Iasi's female population (n = 394,274), a representative sample was determined, allowing for a margin of error of 14.6% at 45 participants.

From 2019 to 2023, the number of hospitalized cases of ovarian endometriosis has shown a rising trend, represented by the equation ($y = 79 + 9x$), with projections indicating around 119 cases for 2024. Similarly, the trend for endometriosis cases that underwent surgery during the same period is also increasing ($y = 57 + 6x$), forecasting approximately 87 cases for 2024, which constitutes 73% of the total predicted cases for that year (fig. 1). Between January and September 2024, there were 64 hospitalizations for ovarian endometriosis, out of which 33 cases (51.6%) resulted in surgery, accounting for nearly half of all hospitalizations related to this condition.

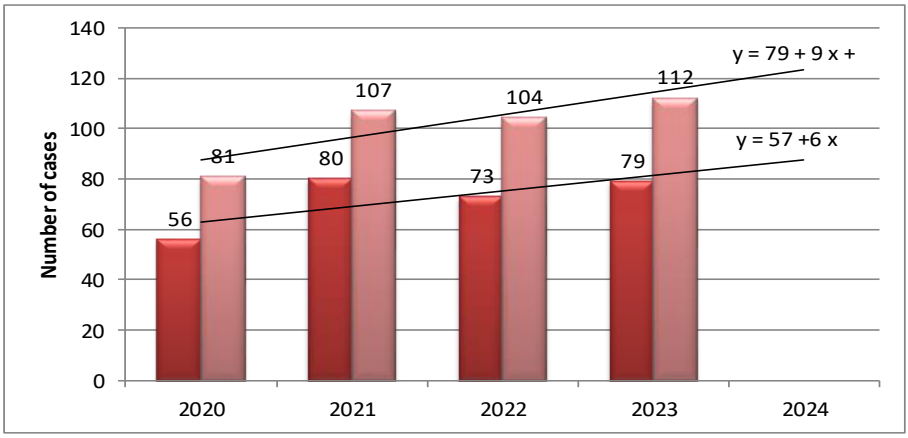

Fig. 1. Distribution of endometriosis cases that underwent surgery between 2020-2023.

Inclusion and exclusion criteria

A prospective study was carried out involving a total of 40 patients assessed at "Cuza-Vodă" and "Elena-Doamna" Obstetrics and Gynecology Clinical Hospitals, Iași between September 2019 to August 2024 of whom 40 met the inclusion criteria and had been underwent surgery. Participants were organized into two groups: an endometriosis group, comprising 35 patients with confirmed endometriosis (30 cases of ovarian endometriosis and five cases with parietal endometriosis), and a control group of 5 patients presenting inflammatory symptoms without histopathological confirmation of endometriosis.

The exclusion criteria applied were lack of signed consent, incomplete follow-up assessments, and absence of histopathological confirmation.

Statistical analysis

This prospective case-control study utilized *SPSS software version 18.0* and data were initially organized and summarized, followed by analyses to derive additional indicators through comparative techniques. Key statistical methods employed included the Student's t-test, the Chi-Square (χ^2) and the Kruskal-Wallis test. The Pearson Correlation Coefficient (r) evaluated the magnitude and direction of associations between variables, and the ROC curve was used to examine the balance between sensitivity and specificity.

The research was carried out in compliance with the Declaration of Helsinki and received approval from the ethics committees of both of the hospitals involved ("Cuza-Vodă" Obstetrics and Gynecology Clinical Hospital No. 130002/24.11.2020, "Elena-Doamna" Obstetrics and Gynecology Clinical Hospital No. 390/13.01.2023), but also of the ethics committees of the "Grigore T. Popa'' University of Medicine and Pharmacy Iasi (No. 401/15.02.2024). Due to the study`s prospective nature, patient consent was necessary. The study's design and data management procedures followed both national and international standards for research involving human participants.

RESULTS

Epidemiological data

Among the participants in the study co-

hort diagnosed with endometriosis, the median age was similar to the mean age (33 years *vs.* 33.03 years), and the Skewness Test results (value <2) indicated a consistent age distribution, justifying the application of statistical significance tests to continuous variables. In patients diagnosed with ovarian endometriosis, aged ranged from 25 to 42 years, with the mean age being higher than that of the other group analyzed, though the difference was not statistically significant, compared to the parietal group (33.60 years vs 32.20 years; p=0.532), and the control group (33.60 years *vs.* 30.40 years; p=0.203).

Demographic characteristics

Demographic analysis of the 40 study participants revealed no significant differences in characteristics between those with endometriosis (n=35) and the control group (n=5). Age distribution was homogeneous across groups (p=0.740), with 20-30% of cases in each group being older than 35 years. In conjunction with the median age of 30 years in the control group, this threshold was chosen for subsequent significance test: 73.3% of patients with ovarian endometriosis and 80% of those with parietal endometriosis were older than 30 years (p=0.747). Urban residency was common with similar distribution across both groups (70% in the ovarian endometriosis cases, 100% in the parietal endometriosis cases and 80.0% in the control patients; p=0.189). Marital status was also relative comparable, married women are including 83.3% of the ovarian endometriosis group, 80.0% parietal endometriosis group and 60.0% of the comparison group (p=0.340). Additionally, the percentage of patients with higher education attainment reported: 63.3% in the ovarian endometriosis cases, 80% in the parietal endometriosis group and 80.0% in the control group (p=0.604). Employment rates were high showing no significant variation between the groups (86.7% for ovarian endometriosis, 100% for parietal endometriosis and 80.0% for control; p=0.454). Smoking prevalence was in the control group 60.0% by comparison with other groups (36,9% ovarian endometriosis and 60% parietal endometriosis) (p=0.436). These balanced demographic characteristics provided a robust basis for comparative analysis.

Clinical characteristics of study participants

The clinical profiles of the patients revealed various features commonly associated with ovarian endometriosis. Primary infertility was present in 53.3% of cases, with a mean duration of infertility exceeding two years in 63.3% of ovarian endometriosis. Hormonal treatment was commonly utilized, particularly among those initially diagnosed with ovarian endometriosis, were 53.3% received treatment for a duration of 1 to 3 years. A smaller percentage, 26.7%, had undergone hormonal therapy for less than one year, while 20.0% had received treatment for a period of 3 to 5 years.

Laboratory findings

Biochemical and hematological assessments revealed significant differences between the two groups. CA-125 levels were markedly higher in those with ovarian endometriosis (67.87±23.61 U/mL) relative to parietal endometriosis (23.32±2.11 U/mL) and controls (22.58±4.8 U/ml, p=0.001). Among inflammatory markers, lymphocyte counts were lower in endometriosis, whereas eosinophil counts, red cell distribution width (RDW) and platelet count were higher in the control group. Although,

the values of the systemic immune-inflammatory biomarkers (neutrophil-to-lymphocyte ratio -NLR-, systemic immune inflammation index -SII, platelet-to-lymphocyte ratio -PLR-) in endometriosis patients were within the range typically observed in the international average scale, the following values were recorded: NLR: 1.76 (0.83-3.92), PLR: 120 (61-239), SII: 459 (189-1168) (tab. I) (9).

TABLE I.

Systemic immune-inflammatory markers

Parameter	Control Group n=5	Ovarian Endometriosis Group n=30	Parietal Endometriosis n=5
NLR	1.96±0.30	3.82±2.07 (p=0.040)	4.17±1.14 p=0.026) p=0.918)
PLR	110.31±23.19	183.18±54.62 (p=0.012)	166.75±30.11 p=0.188) p=0.776)
SII	696.15±193.84	1034.50±623.08 (p=0.044)	964.88±258.75 p=0.050) p=0.964)

In patients with ovarian endometriosis, the correlation of mean values for the inflammatory parameters according to the rASRM staging revealed significantly lower values in stage IV for the neutrophil-to-lymphocyte ratio (NLR) (2.68 *vs.* 4.81; p = 0.003), platelet-to-lymphocyte ratio (PLR) (156.70 *vs.* 206.35; p = 0.01), and systemic immune inflammation index (SII) (721.54 *vs.* 1308.34; p = 0.008) (tab. II).

TABLE II.

Association of inflammatory markers with rASRM staging in patients with ovarian endometriosis

Parameter	Stage III (rASRM) (n=16)	Stage IV (rASRM) (n=14)	t-Student test p
NLR	4.81±2.01	2.68±1.51	**0.003**
PLR	206.35±62.89	156.70±26.00	**0.010**
SII	1308.34±661.82	721.54±403.57	**0.008**

In patients with recurrent ovarian endometriosis, the correlation of mean values for inflammatory parameters according to rASRM staging demonstrated significantly lower values in stage IV for the neutrophil-to-lymphocyte ratio (NLR) (2.80 *vs.* 6.17; p = 0.027), platelet-to-lymphocyte ratio (PLR) (160.25 *vs.* 257.61; p = 0.046), and systemic immune inflammation index (SII) (760.63 *vs.* 1870.95; p = 0.034) (tab. III).

TABLE III.

Association of inflammatory markers with rASRM staging in patients with recurrent ovarian endometriosis

Parameter	Stage III (rASRM) (n=2)	Stage IV (rASRM) (n=3)	t-Student test p
NLR	6.18±1.53	2.80±0.29	**0.027**
PLR	257.61±83.03	160.25±5.38	**0.046**
SII	1870.95±709.14	760.63±175.01	**0.034**

Among the 30 patients with ovarian endometriosis, following surgical intervention, only 27 retained the potential for spontaneous conception. The correlation of the mean values of systemic inflammatory parameters according to the EFI index was not statistically significant ($p > 0.05$).

Additionally, the coagulation profile showed shorter activated partial thromboplastin time (APTT) and prothrombin time (PT) in the endometriosis group, while only a minor variation in urinary density was observed.

TABLE IV.

Association of systemic inflammatory markers with the EFI index

Parameter	EFI< 5 n=10	EFI = 5-7 n=14	EFI ≥8 n=3
NLR	4.50±1.99	3.20±2.04 p=0.319)	4.65±2.96 p=0.993) p=0.537)
PLR	178.16±56.86	211.39±86.36 p=0.958)	211.39±86.36 p=0.784) p=0.662)
SII	1270±612	817±528 p=0.203)	1457±1055 p=0.891) p=0.255)

Histopathological findings

By examining tissue characteristics and structural depth, histopathology helps categorize endometriosis into three clinically relevant subtypes. Superficial peritoneal endometriosis manifested as small, shallow implants on the peritoneum and was generally linked to milder symptoms and lower stages (10). Ovarian endometriomas, often identified as cysts containing old hemorrhagic material, were characterized by endometrial epithelial lining on the cyst wall (fig. 4). For instance, one case (fig. 2) displayed an ovarian cyst wall lined with endometrial stroma and glands (H&E x4), while another (fig. 3) showed endometrial gland inclusion within the tubal wall, highlighting tubal involvement (H&E x4). DIE lesions were marked by infiltration deeper than 5 mm into pelvic structures, including areas such as the rectovaginal septum, and were often correlated with severe pain and elevated inflammatory markers, evidenced by higher CA-125 levels and increased ASRM stages. Hormone receptor analysis indicated elevated estrogen receptor expression in DIE lesions, possibly contributing to their invasive behavior and reduced responsiveness to hormonal therapies in advanced cases.

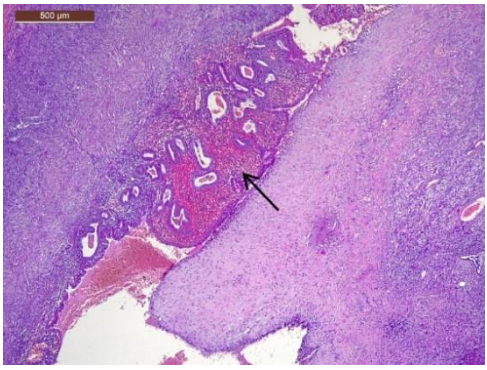

Fig. 2. Ovarian cyst wall showing cortical layer lined with endometrial stroma and glands (arrow) (HE, x4)

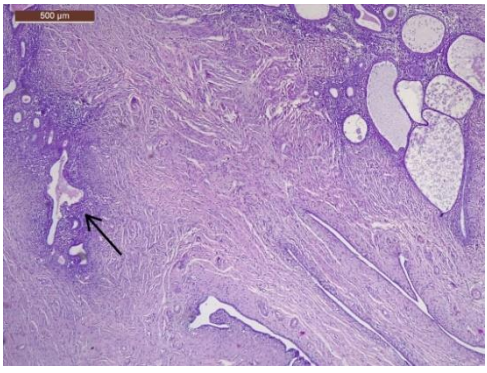

Fig. 3. Tubal wall of the same patient, showing inclusion of endometrial glands and stroma in the tubal wall (arrow) (HE, x4)

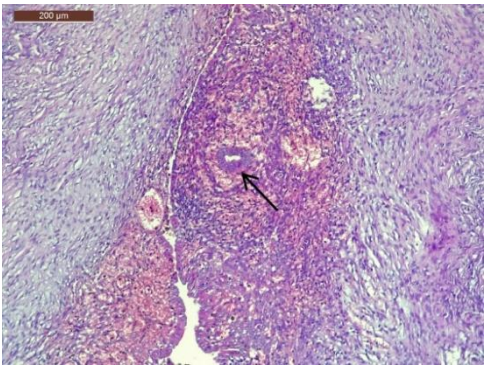

Fig. 4. Ovarian cyst lined with endometrial stroma and gland (arrow) (HE, x10).

DISCUSSION

Endometriosis continues to be a complex and multifaceted condition, significantly impacting both physical and mental well-being. This study provides insights into the intricate relationships between clinical symptoms and histopathological features, adding to the existing literature and offering a detailed perspective on diagnosis and management strategies for endometriosis. Consistent with previous studies, our results suggest that demographic factors, including age and lifestyle, although statistically nonsignificant, may influence disease severity and symptom presentation (11, 12). The association observed between infertility and elevated CA-125 levels aligns with findings from Horne *et al.* (2022), underscoring the relevance of inflammatory biomarkers in diagnosing and predicting endometriosis outcomes (6). In 2018, Fest *et al.* in *Nature*, associated chronic inflammatory pathologies with novel prognostic markers (NLR, PLR, SII) and provided their average reference values in a cohort of 8,711 patients aged up to 45 years (9). High CA-125 levels, along with inflammatory markers such as the NLR and PLR, further highlight the systemic inflammatory nature of endometriosis, emphasizing its immunological aspect. This finding is in line with recent research on emerging biomarkers by Zondervan and Becker, which supports the inclusion of biomarker analysis in routine clinical practice (13). Additionally, the prevalence of primary infertility and extended hormonal treatment durations highlights the necessity for more individualized therapeutic strategies, Current guidelines support a patient-specific approach based on clinical staging and hormonal profiles, as noted by Zondervan *et al.* (2020) (1). Integrating these findings with current recommendations, particularly concerning the timing and dosage of hormonal treatments, could enhance reproductive outcomes for patients at various stages of the disease. The absence of a straightforward correlation between rASRM staging and symptom severity remains a subject of debate, as similar inconsistencies have been noted in other studies. This lack of direct alignment suggests that staging should be supplemented with histopathological assessments, including hormone receptor analysis, to improve predictions of treatment responses and long-term outcomes (14). Emerging literature advocates for this approach, proposing that histopathological data could serve as valuable adjuncts to refine the rASRM classification, especially in distinguishing between deep infiltrating and ovarian endometriosis subtypes (15). In our study, in terms of systemic inflammatory markers, the rASRM classification identifies lower values in stage IV compared to stage III, while the EFI classification does not reveal any significant changes.

This study highlights the value of correlating clinical and histopathological findings in endometriosis, supporting a multidisciplinary and personalized approach to treatment. Future research should focus on

non-invasive diagnostic tools and further exploration of the inflammatory and immunological pathways involved, potentially leading to new options for targeted therapy.

CONCLUSIONS

This study emphasizes the significance of examining both clinical characteristics and histopathological features in understanding endometriosis. The associations observed between inflammatory biomarkers-such as elevated levels of CA-125, NLR, PLR, and SII-compared to the control group, suggest that endometriosis involves a systemic inflammatory component, rather than being limited to localized pathology (13, 15). These findings endorse the use of biomarkers as supplementary diagnostic tools, which could potentially enable earlier and more precise diagnoses in clinical practice.

The inconsistency between ASRM staging and symptom severity underscores the need for an expanded diagnostic framework. By incorporating histopathological evaluations, including lesion morphology, the accuracy of staging can be improved, allowing for a more tailored treatment approach (14). Such an individualized approach in endometriosis is essential both for fertility management and for the patient's quality of life.

Moreover, the association of CA-125, systemic inflammatory markers, and rASRM staging may provide the foundation for the identification of novel non-invasive biomarkers, as well as potential prognostic factors for endometriosis.

In summary, the findings of this study advocate for a comprehensive diagnostic approach to endometriosis that integrates clinical, histopathological, and inflammatory markers. Future research should prioritize the development of non-invasive diagnostic methods and further investigate the immunological mechanisms underlying endometriosis, which could open new avenues for effective, targeted therapies (13). The endometriosis continues to pose significant surgical challenges; however, the integration of advanced artificial intelligence techniques in ultrasonography offers the potential to enhance the precision of subsequent surgical decision-making (17-20).

ACKNOWLEDGEMENTS

The authors would like to acknowledge the support of “Cuza-Vodă” and “Elena-Doamna” Obstetrics and Gynecology Clinical Hospitals, Iași for providing the facilities and access to medical records necessary for this research. We mention the distinguished appreciation of the “Grigore T, Popa University of Medicine and Pharmacy Iasi for the support granted the Ph.D. student Toma Bogdan Florin by financing the doctoral grant. Special thanks to the medical staff involved in patient data collection and analysis, whose contributions were invaluable in completing this study.

CONFLICT OF INTEREST

The authors declare no conflict of interest regarding the publication of this article.

EFFICACY AND SAFETY OF IMAGING-GUIDED TRANSTHORACIC NEEDLE LUNG BIOPSY - A REAL-LIFE STUDY (Abstract): Despite global efforts, the challenge of early-stage diagnosis of lung cancer persists. To improve diagnose of peripheral lung tumors, a less invasive, cost-effective, and time-efficient sampling technique is essential. Percutaneous imaging-guided transthoracic lung biopsy meets these criteria. **Aims:** This study aims to determine the efficacy of imaging-guided transthoracic needle lung biopsy and to identify periprocedural complications and diagnostic success rate in a tertiary pulmonology center. **Materials and methods:** We conducted in "Marius Nasta" Institute of Pulmonology, from Bucharest, Romania, a retrospective, observational study on consecutive patients diagnosed with lung, pleural or chest wall tumors that underwent transthoracic Computed-Tomography (CT)-scan guided needle biopsy or ultrasound (US)-guided needle biopsy. The efficacy and safety of these procedures were assessed. **Results**: We enrolled 280 patients, with 261 undergoing CT-scan transthoracic guided percutaneous needle biopsy and 19 undergoing US-guided needle biopsy, between 2021 and 2023. Histopathological results were obtained in 267 cases (95.35%) of lung biopsies, with only 13 (4.64%) inconclusive specimens. The reports identified 225 (80.35%) malignant tumors and 42 (15%) other diseases. Out of 225 malignant tumors, 193 (85.77%) were NSCLC. Out of NSCLC 103 were lung adenocarcinomas (53.36%). Periprocedural complications rate was 23.22%, mainly pneumo-thorax, hemoptysis and alveolar hemorrhage. No fatal outcome was recorded. **Conclusions**: The study underscores the efficacy of percutaneous CT-guided or US-guided transthoracic needle lung biopsy in clinical practice, with an affordable risk of complications. The implication of a multidisciplinary team is essential for the best outcome. **Keywords**: LUNG CANCER, HISTOPATHOLOGICAL TYPE, CT-GUIDED TRANSTHORACIC LUNG BIOPSY, US-GUIDED TRANSTHORACIC LUNG BIOPSY.

INTRODUCTION

In 2022, according to the European Cancer Information System, the European Union (EU27) alone estimated a total number of 319,236 new cases of lung cancer (incidence rate 71.5 per 100,000). It is the

second most diagnosed cancer in men (incidence rate 93 per 100,000) after prostate cancer and the third after breast and colorectal cancers in women (incidence rate 50.9 per 100,000). It ranks as the second most frequent malignancy with an estimated total number in the EU27 of 803,644 cases (prevalence rate 170.4 per 100,000). In Romania 11,716 new cases were diagnosed (incidence rate 61.5 per 100,000), with a significant difference between men (incidence rate 92 per 100,000) and women (incidence rate 32.8 per 100,000). The prevalence rate in Romania was 143.6 per 100,000 (27,016 total cases). Additionally, lung cancer stands as the leading cause of cancer-related mortality, with a mortality rate of 18 per 100,000 people (1).

Despite these staggering statistics and world-wide efforts to improve survival rates, early-stage diagnosis remains challenging. Early diagnosis and treatment of small, localized lung tumors is highly recommended. To facilitate this, a tumoral lung biopsy and histopathology confirmation are mandatory. The sampling technique should be less invasive, cost-effective, with a lower complication rate, and more time-efficient for medical staff compared to classical surgical methods. While ultrasound (US)-guided transbronchial lung biopsy is efficient for contiguous lesions, it faces challenges for peripheral ones (limited availability of endobronchial-navigation equipment). Despite their high diagnostic success rate, open lung biopsy and video-assisted thoracoscopic surgery (VATS) come with restriction related to poor clinical status of some patients and greater morbidity and complications (2). A proposed alternative solution meeting the outlined criteria is imaging-guided transthoracic needle lung biopsy.

This study aims to determine the efficacy of imaging-guided transthoracic needle lung biopsy in "Marius Nasta" Institute of Pulmonology, Bucharest, Romania, a tertiary pulmonology center, and to identify periprocedural complications and diagnostic success rate.

MATERIALS AND METHODS

We conducted a retrospective, observational study on consecutive patients diagnosed with lung, pleural or parietal tumors that underwent transthoracic Computed-Tomography (CT)-scan guided needle biopsy or ultrasound (US)-guided needle biopsy, between 2021 and 2023. All patients were hospitalized. Coagulation tests (Prothrombin Activity, Activated Partial Thromboplastin Clotting Time, International Normalized Ratio), along with a total blood cell count and other routine analyses, were conducted before the procedure. Additionally, medications for bleeding control and platelet function were adjusted or ceased according to international guidelines.

For all subjects, bronchoscopy was performed previously and endobronchial or transbronchial biopsies were not possible or were inconclusive for histopathology diagnosis. All cases were selected by a team consisting of a pulmonologist, a radiologist and a thoracic surgeon. The procedure was made by a specialized radiologist, in the presence of a thoracic surgeon prepared for immediate intervention, if needed.

We made a rigorous patient selection, considering the following indications:

- New or growing solitary nodules (more than 8 mm in diameter) or masses on chest imaging that are not amenable to diagnosis by bronchoscopy or are unlikely to be accessible by bronchoscopy;
- Multiple nodules in a patient not known to have malignancy or who has experienced prolonged remission or has more than one primary malignancy;

- Persistent focal infiltrates or consolidations, either single or multiple, for which no diagnosis has been made by sputum or blood culture, serology, or bronchoscopy;

We used 16-slice computed tomography scanner Neusoft (CT-guided) and a 5 MHz curvilinear (ultrasound guided). Regarding the needles, Medax Medeasy semi-automatic spring-loaded biopsy system was used, with 16, or 18 gauge.

Informed consent was obtained from all patients after an extensive discussion. Relevant blood tests and radiological exams were reviewed prior to the procedure. In order to facilitate the safest and most effective needle pathway, the patient was positioned accordingly: supine, prone or lateral decubitus. A first CT-scan acquisition of the thorax was performed to locate the target lesion and to determine the entry level, where a dotted line of radio-opaque markers was applied on patient's skin. A second volumetric CT scan was done, centered on the markers and including the entire target lesion. A specific entry point from the line was chosen. Then, on the disinfected area (using povidone-iodine) local anesthesia with 1% lidocaine was performed. Using measurements and repeated CT scans of that range the introducer needle was positioned in the target lesion. Biopsies were performed using a 16G or 18G coaxial semiautomatic biopsy device with adjustable sample notch (10 mm/20 mm). Needle size, sample number and length depend on lesion dimensions, degree of necrosis, risk of complications and patient status. The number of specimens collected ranged between 1 and 8 fragments. Fragments were placed in a labelled recipient containing 4% formaldehyde solution and sent to the histopathology lab.

For ultrasound guided procedures, suitable patients were selected, and a 5 MHz curvilinear probe was used for biopsy guidance. A 16G or 18 G semiautomatic biopsy needle was used directly without the coaxial to remove the samples.

All patients were monitored: CT-scan immediately after procedure and a chest X-ray 2 hours after. If stable, elective patients without signs of complications were discharged in the same day. The others were monitored for 24 hours in the hospital.

All data were collected from the hospital's electronic medical record database and personal identification data of the patients were anonymized.

Patients consented for using the data for scientific purposes with the condition of anonymity. The approval of the study by the Ethics Committee of the Institute was obtained.

Statistical correlations were generated in *SPSS version 29.0.2.0* (IBM), while the database was collected and organized in Microsoft Office Excel. The results were expressed as mean values ± standard deviation or as an absolute number (percentages). The results were considered statistically significant for a value of $p<0.05$, and were represented using graphs, histograms and tables.

RESULTS

A number of 280 consecutive patients that underwent CT-guided or US-guided transthoracic needle biopsy for lung, pleural or chest wall tumors were included.

Regarding the types of guidance for transthoracic needle approach, we used two types of imaging guidance: computed tomography (261 cases) and ultrasound (19 cases). Ultrasound guidance was more frequently used for pleural histopathology, chest wall involvement and peripheral lung lesions (3).

From the total number of patients, 189 were males (67.5%) with a gender ratio was M: F = 2.07: 1. The mean age was

62.99 years ± 10.92 SD (fig. 1).

Regarding smoking status, 135 patients were smokers or former smokers (48.21%), 20 patients were non-smokers (7.1%), and for 125 patients (44.6%), we were not able to find data about smoking history in database. Occupational exposure was seen in 71 patients (25.35%).

Regarding comorbidities, 132 patients (47.14%) had respiratory diseases (fig. 2).

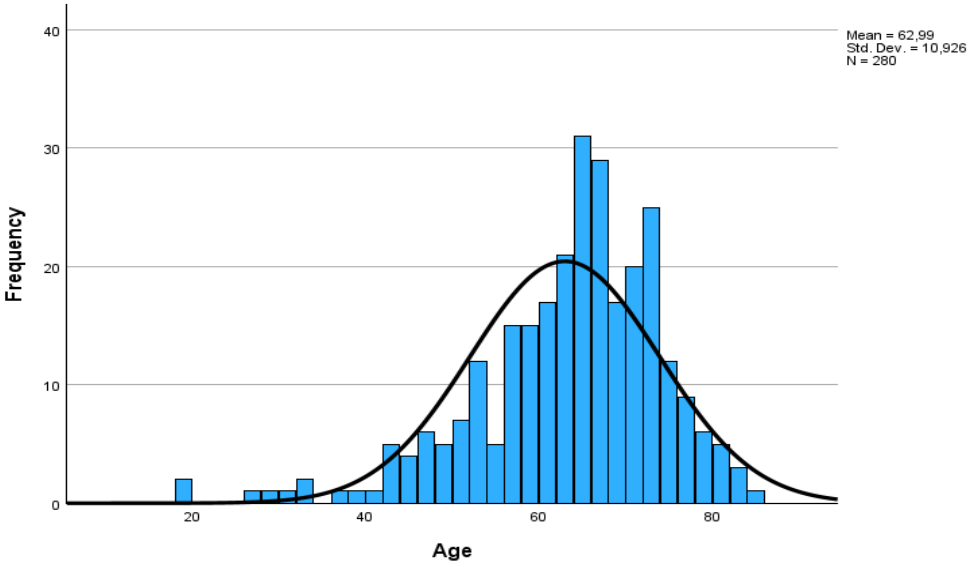

Fig. 1. Age distribution of the patients

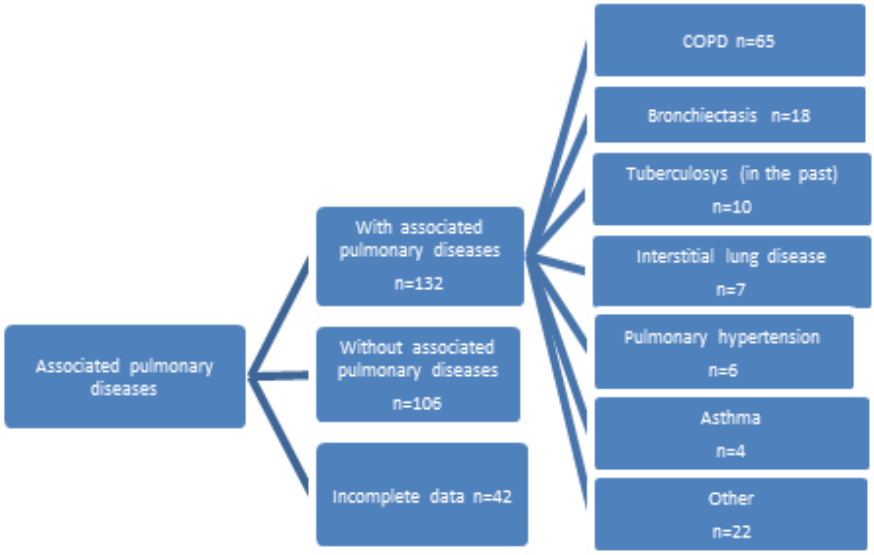

Fig. 2. Distribution of pulmonary comorbidities

The main pulmonary disease was chronic obstructive pulmonary disease (65 patients). A number of 191 subjects had other comorbidities, mainly cardio-vascular and metabolic disorders (fig. 3).

Anemia is only present in 12 patients, while 50 subjects had no other diagnosis.

Out of 280 imaging-guided transthoracic needle biopsies, 267 were diagnostic (95.35%). Only 13 biopsies were inconclusive. Positive results for malignant tumors were obtained in 225 cases (84.26%). Lung cancer was the most frequent (194 cases) with only one case of Small-Cell Lung Cancer (SCLC) and 193 cases of Non-Small-Cell Lung Cancer (NSCLC), with the following subtypes: adenocarcinomas (103 cases, 53.36%), NSCLC-no other specified (NOS) (47 cases, 24.35%), Squamous Cell Carcinoma (32 cases, 16,58%) and undifferentiated carcinoma (11 cases, 5.69%).

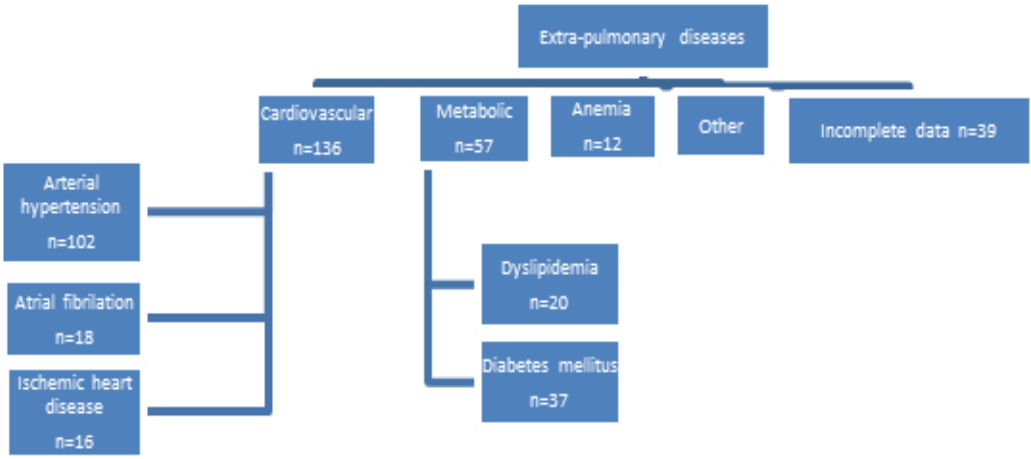

Fig. 3. Extra pulmonary comorbidities distribution

In other 31 cases, malignancy was confirmed, as following: 12 metastases from other distant malignant tumors, 4 neuroendocrine origin tumors other than SCLC, 5 Non-Hodgkin lymphomas, 3 lymphoproliferative malignant disorders, 1 sarcoma, 1 plasmacytoma and 5 only malignant tumoral aspect without definite histopathological pattern.

Among the remaining results, from the 267 conclusive results, 28 cases (10.48%) had “no tumoral aspect”. Additionally, 14 cases (4.86%) were benign lesions: 8 chronic inflammation, 2 pulmonary tuberculosis, 2 fibrinoid pleural mass, 1 organizing pneumonia, and 1 case of thymoma (fig. 4).

Post-procedural complications were seen in 23.22% of procedures (65 cases): 51 cases of small to mild pneumothorax (18.21%), 10 alveolar hemorrhage (3.57%), 7 hemoptysis (2.5%), and 2 subcutaneous emphysema (0.71%) (fig. 5). No severe nor fatal outcome occurred.

DISCUSSION

Lung cancer remains a major contributor to cancer-related morbidity and mortality worldwide. Achieving an accurate diagnosis is essential for guiding effective treatment strategies, with histopathological examination serving as a cornerstone in the diagnostic process for pulmonary tumors. Two minimally invasive techniques, bronchoscopy and CT-guided transthoracic biopsy, have proven instrumental in obtaining tissue samples for histological analysis. For centrally located tumors, bronchoscopy is the preferred method, offering direct access to the lesion. However, peripheral tumors pose a greater challenge for tissue sampling. While surgical approaches, such as classical thoracotomy or video-assisted

thoracoscopy (VATS), are highly effective for obtaining biopsies, they are invasive. A less invasive alternative is imaging-guided transthoracic needle biopsy, which uses CT or ultrasound guidance to target and sample peripheral lesions. Histopathological analysis of tissue samples obtained via these methods enables precise tumor characterization, including subtyping of non-small cell lung cancer (NSCLC) versus small cell lung cancer (SCLC), and assessing molecular biomarkers crucial for personalized therapy. This multimodal diagnostic approach plays a vital role in early detection, staging, and treatment planning of lung cancer, improving patient outcomes in this challenging disease.

The aim of this study was to determine the efficacy of imaging-guided transthoracic needle lung biopsy in a tertiary pulmonology center in Romania, and to identify periprocedural complications.

Out of 280 consecutive patients that underwent CT-guided or US-guided transthoracic needle biopsy for thoracic tumors, 267 yielded a definitive diagnosis, resulting in a diagnostic accuracy of 95.35%. This aligns with data reported in the literature, which highlights a high diagnostic success rate ranging from 78%-85% (4-6) to 92.9%-96.8% (7, 8). However, for nodules smaller than 1.5cm, the diagnostic rate is lower (9). These favorable outcomes were achieved through a multidisciplinary team approach involving pulmonologists, radiologists, and thoracic surgeons. This collaborative team carefully selected candidates for the procedure, maintaining a balance between benefits and potential risks. An important issue is to exclude extensive necrosis of the tumor, honeycombing, and large emphysema areas. High risks patients, for which the benefits would have been limited, were not accepted to undergo the procedure. For example, the case of a patient with a history of pneumonectomy due to lung cancer (10 years before the actual evaluation) and extensive emphysema with a lung nodule was rejected due to high risk of respiratory failure.

Out of 267 confirmed cases, 225 were malignant tumors, lung cancer being the most prominent (194 cases). This distribution is according to our expectations, given the hospital's focus on pulmonary diseases.

Positive results for malignant tumors were obtained in 225 cases (84.26%). Lung cancer was the most frequent (194 cases), 193 cases being Non-Small-Cell Lung Cancer (NSCLC). Pulmonary adenocarcinoma was the most prevalent (103 cases, 53.36%), which is similar to other study where 60% were adenocarcinomas (10), reinforcing the well-established trend of adenocarcinoma predominance in the last decade. This is probably due to peripheral location of the adenocarcinomas (11), that means that imaging-guided transthoracic needle biopsy is the appropriate tool to manage this situation. Other histopathological types were: NSCLC-no other specified (NOS) (47 cases, 24.35%), Squamous Cell Carcinoma (32 cases, 16,58%) and undifferentiated carcinoma (11 cases, 5,69%). For NSCLC-NOS specimens were sent to immunohistochemistry analysis to better characterize the tumor.

Statistical analysis revealed a significant correlation between COPD and malignant results (p=0.019; CI=95%), as both diseases are smoke-related diseases.

Among the non-malignant results, 28 cases (10.48%) had “no tumoral aspect”, and 14 cases (4.86%) were benign lesions: 8 chronic inflammation, 2 pulmonary tuberculosis, 2 fibrinoid pleural mass, 1 organizing pneumonia, and 1 case of thymoma. We noticed only 2 cases of pulmo-

nary tuberculosis aligned with the decreasing incidence of tuberculosis in Romania in the last decade.

In order to identify possible complications associated with the technique, a thoracic CT scan was performed immediately after the procedure, and an additional chest X-ray was done 2 hours later. These were performed to assess the presence of pneumothorax, hemothorax, or alveolar hemorrhage. Complications, such as pneumothorax, hemoptysis, alveolar hemorrhage and air embolism may occur in 25.8%, as described in one meta-analysis (12). Pneumothorax was the main complication, between 23.3 and 25.9% as in one large meta-analysis on 23,104 patients (13). Higher frequency was observed in elderly individuals with underlying diseases such as emphysema or honeycombing (14).

Our study shows a post-procedural complications rate of 23.22% with 65 cases of complications, but none of them being severe or lethal. We reported small to mild pneumothorax in 18.21% of cases, alveolar hemorrhage 3.57%, hemoptysis 2,5%, and subcutaneous emphysema in 0,71% of cases. Notably, lesions located in the lower lobes were associated with a significantly higher risk of complications (p=0.043; 95% CI).

Periprocedural complication rates appeared higher with age (p=0.046; CI=95%). Underlying COPD, diabetes mellitus, anemia, chronic heart failure, atrial fibrillation, arterial hypertension did not significantly correlate with complications (p>0,05). The lack of correlation might suggest the high safety profile of the procedure.

Additionally, the number of samples was not correlated with complications (p=0.069; CI=95%). The number of specimens collected ranged between 1 and 8 fragments, with a mean value of 3.03+/-1.15. As mentioned before, we did not determine the quantity and/or the quality of the specimens. Although this study's purpose was not to evaluate a standardized quality and quantity of the samples, we observed that a higher number of samples was not significantly correlated with a suitable, conclusive biopsy (p=0.069; CI 95%), which might suggest that the quality of specimens may be more important. Moreover, advanced lung cancer (presence of metastasis) does not correlate with higher diagnostic rate (p=0.35; CI 95%), though, regarding the technique, CT-guided technique tended to offer a higher number of fragments (p=0.01; CI 95%).

Limitations of the study: Data regarding smoking or exposure status was limited due to the patient's refusal to provide the information or the information not being tracked in the available documents. Another constraint encountered is the availability of internal immunohistochemistry infrastructure. In this situation, immunohistochemistry tests were done by external laboratories for multiple samples.

CONCLUSIONS

This study underscores the significance of a less invasive, cost-effective technique with a lower complication rate for lung biopsy. The success diagnostic rate is 95.35% and is not correlated with higher number of fragments, highlighting the importance of a quality specimen. Further studies might include a standardized qualitative and quantitative analysis of the samples in order to validate the hypothesis. Complication rate of the procedure significantly correlates with older age, and lower lobes localization.

Lung adenocarcinoma diagnosis was the main histopathological subtype of lung cancer diagnosed by this procedure.

In our center, imaging-guided lung biopsy has significantly reduced the time between detecting suspicious lung lesions and initiating appropriate oncological treatment (once confirmed). The implication of a pneumologist-radiologist-thoracic surgeon team is essential, as they proceed to select the patients in order to minimize inconclusive samples and to evaluate risk benefits ratio.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflicts of interests. The research did not receive external funding.

ORAL HEALTH BEHAVIORS IDENTIFIED IN PATIENTS ACCESSING DENTAL EMERGENCY UNITS. A SINGLE CENTER STUDY (Abstract). **The aim** of the study was to identify the profile of patients accessing dental emergency units. **Materials and methods**: A total of 105 patients who accessed emergency units completed a questionnaire. Socio-demographic, medical, and health-related behavioral data were collected. Additionally, medical diagnostics were considered for this research. **Results**: Significant differences were identified concerning sex, indicating that men visited emergency units more frequently in the previous month (1.76 ± 0.43) than women (1.54 ± 0.50). Patients with chronic diseases were more commonly diagnosed with periodontitis and mucosal lesions, and they used less analgesic treatment for dental pain than patients with non-chronic diseases. Age correlated positively with a diagnosis of gingivitis ($r = 0.19$, $p = 0.04$), in the sense that older individuals were more likely to be diagnosed with gingivitis. The results also proved a strong positive correlation between the level of satisfaction regarding dental health and oral hygiene. The study further investigated the importance of marital status, parenthood, and oral health behaviors. **Conclusions**: Socio-demographic and medical data, along with health-related behaviors, are important factors to be considered when providing emergency dental care to patients. Such information helps dentists and policymakers to shape preventive strategies that reduce the number of unhealthy behaviors and oral health issues in patients accessing emergency dental units. **Keywords:** DENTISTRY, PUBLIC DENTAL EMERGENCY UNIT, DENTAL ANXIETY SCALE, ORAL DISORDERS, QUALITY OF ORAL HEALTH.

INTRODUCTION

According to the Global Oral Health Status Report published by the World Health Organization (WHO) in 2022, 2 billion people suffer from caries of permanent teeth, and 514 million children suffer from caries of primary teeth. A global statistical evaluation estimated that 3.5 billion people worldwide (almost 50% of the population) present oral diseases, the most common being dental caries, periodontal disease, oral cancer, oro-dental trauma, or total tooth loss.

Apart from genetic factors or the presence of comorbidities, most oral health-related problems could be prevented by

limiting alcohol consumption, eliminating the consumption of tobacco, ensuring balanced nutrition and a sugar-free diet, adopting safety measures such as using protective equipment during sports and travel, and brushing teeth with fluoride-containing toothpaste (WHO, 2022) (1). Finally, prioritizing overall quality of life, including physical, mental, and social well-being, while maintaining good health and identifying diseases that negatively impact oral health in proper time could prevent oral health-related problems. Therefore, prevention measures such as promoting good health by adopting a healthy diet, a daily dental cleaning routine, and regular dental checkups are among the most important methods to maintain good dental health and quality of life (Jain *et al.*, 2024) (2). Many factors are associated with low quality of oral health life (OHL): sex, age, level of education, financial income, oral health literacy, and oral health-related behaviors (Fisher *et al.*, 2023) (3). Hakeberg and Boman (2017) identified that the lower the socioeconomic position, the poorer the health (4). Tooth brushing less than three times a day and irregular flossing were additional outcomes associated with low OHL (Batista *et al.*, 2017) (5). Poor oral health literacy was found to be independently associated with missed dental appointments (Baskaradoss,2016) (6). These important factors have been pointed out by many other studies. For example, Ueno *et al.* (2013) (7) found that higher oral health literacy leads to more frequent brushing and better oral hygiene. Similarly, Lee *et al.* (2012) (8) demonstrated a strong positive relationship between increased oral health literacy and improved oral hygiene. This study aimed to shape the profile of patients accessing public dental emergency units in the Oradea area, focusing on dental anxiety and the impact of oral disorders on general well-being.

MATERIALS AND METHODS

Participants and Data Collection. The study was conducted in the public dental emergency unit of the Oradea Emergency Hospital. In 2021, clinical records showed that there were 2,260 patients (1,682 adults and 578 children) with a median average of 188 patients per month. A total of 197 patients, both adults and children, were registered for the period June 20th - July 20th in the dental public emergency unit. Printed questionnaires were distributed to patients waiting to undergo dental consultation. The patients were informed about the purpose of the study, about the confidentiality of the collected data, and about their right to withdraw at any time with no consequences. No incentives were offered for those who participated in the research. Completed surveys were collected in a sealed box located in the main hall. The inclusion criteria consisted of patients aged over 18, fully completed questionnaires, and questionnaires completed by the patients themselves and not by their caregivers. This last criterion was applied to select patients (being literate, assuming self-accuracy of data, and having a normal cognitive level of understanding). Ultimately, a

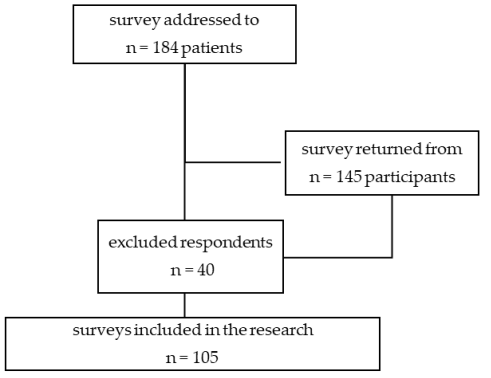

Fig. 1. Study profile.

total of 105 questionnaires were included in the research.

Instruments

A questionnaire was constructed especially for the present study, consisting of 3 parts:

- The first part collected socio-demographic and financial data such as sex, age, environment, marital and professional status, number of children, and monthly income).
- The second part contained self-rated items aimed at collecting information about health-related behaviors, the level of stress, and the quality of dental life (e.g., the presence of a chronic disease, the consumption of alcohol or tobacco, the dental hygiene routine, the consumption of pain drugs, and visits to the dentist. The patients were also required to self-rate certain questions targeting the level of pain or the satisfaction with their dental quality of life (e.g., *How do you rate your level of pain now, on a scale from 1-10,* where 1 represents "no pain")
- The third part of the questionnaire was completed by dentists, recording data about diagnostic, identified dental issues, and emergency interventions.

Statistical Analyses. All data analyses were performed using the *IBM Statistical Package for Social Sciences (SPSS) version 26* (SPSS Inc., Chicago, IL, USA). The descriptive statistics of socio-demographic and medical data were expressed as means and standard deviations (SD), frequencies, and percentages. Given that the distribution of data was normal, parametric tests were used. An independent T-test was performed for the comparative analysis among genders, and a One-Way ANOVA was performed for the comparative analysis among professional categories. Correlation analysis was performed using *Pearson* correlations. The level of statistical significance was set at $p < 0.05$.

Ethical Approval. The present study was conducted in accordance with the Declaration of Helsinki, and the protocol was approved by the Ethical Committee of the Emergency Clinical Hospital of Oradea, Romania, No. 14518.16.06.2021.

RESULTS

Sociodemographic and Medical Data

A total of 105 patients, aged 37.03 ± 14.45 (with a minimum of 18 and a maximum of 84 years old), agreed to fill in the questionnaire. The majority of the respondents were from urban areas and were female (52.4%). Almost three-quarters of them declared that they were employed, with half having a high-school level of education. Additionally, three-quarters of them stated that they were in a relationship, and most of them were parents (tab. I).

Oral health behaviors

The respondents were asked to answer some questions focusing on their oral health-related behaviors. The data analysis revealed that one-third of them consumed alcohol or cigarettes. Three-quarters stated that they used toothpaste and a brush for cleaning their teeth. Less than one-fifth reported using mouthwash, and none of the respondents used dental floss as a method for cleaning their teeth. Regarding their teeth-brushing routine, we identified that around one-third of them brushed their teeth in the morning or at night, with morning brushing being more common than evening brushing (tab. II).

The diagnostics were registered by the medical team, and all details are presented in table III.

There were significant differences in calling for dental consultation services between males and females, $t(103) = 2.336$, $p = 0.021$. Results proved that men had visited the dentist more often in the previous month (1.76 ± 0.43) compared with women (1.54 ± 0.50).

A statistically significant difference was observed in the examination of swellings between male and female patients, with women showing a higher mean number of swellings (1.22 ± 0.42) than men (1.00 ± 0.00), t(17) = -2.204, p = 0.042. An independent-sample T-test was performed to determine if there were differences in analgesic administration between patients with chronic diseases and healthy patients. Results showed that on average, patients who did not suffer from chronic diseases took more analgesics (1.44 ± 0.49) than patients suffering from chronic diseases (1.12 ± 0.35), t(9.47) = -2.360, p = 0.041.

Significant differences were observed in the examination of mucosal lesions between patients with and without chronic diseases $t(93) = 3.511$, $p = 0.001$, meaning that respondents with chronic diseases showed a higher mean number of mucosal lesions (2.00 ± 0.00) than healthy respondents (1.88 ± 0.32). Furthermore, results indicated that patients who suffered from chronic diseases were more frequently diagnosed with periodontitis (2.00 ± 0.00) than those who did not (1.94 ± 0.24), t(96) = 2.516, p = 0.014.

There were significant differences in examining swellings based on marital status, $t(23) = -2.145$, $p = 0.043$. Participants engaged in a relationship showed a higher mean number of swellings (1.17 ± 0.38) than single participants (1.00 ± 0.00). The statistical analysis of data indicated that single patients were more frequently diagnosed with periodontitis (2.00 ± 0.00) than patients who were engaged in a relationship (1.92 ± 0.27), t(73) = 2.538, p = 0.013.

A one-way ANOVA was conducted to determine if the diagnosis of dental fillings varied among groups with different levels of education. Participants were classified into four groups: *those with primary school education* ($n = 7$), *those with secondary school education* ($n = 13$), *those with high school education* ($n = 69$), and *those with higher education* ($n = 14$). The data are presented as mean ± standard deviation, and there was homogeneity of variances, as assessed by Levene's test of homogeneity of variances ($p = 0.771$). The diagnosis of fillings was statistically significantly different across education levels, $F(3, 99) = 6.837$, $p < 0.001$, showing an increase from higher education (1.43 ± 0.51) to high school (1.57 ± 0.60), to secondary school (1.92 ± 0.76), and finally to primary school (2.57 ± 0.78), in that order. Tukey post hoc analysis revealed that the increase from primary to secondary school education (1.006, 95% CI (0.36 to 1.66)), ($p = 0.001$) as well as the increase from primary school to higher education were statistically significant (1.143, 95% CI (0.38 to 1.90)), ($p = 0.001$), but no other group differences were statistically significant.

Another analysis using one-way ANOVA was conducted to determine if the number of children varied across different professional groups. The participants were classified into five groups: *students* ($n = 8$), *employees* ($n = 73$), *pensioners* ($n = 10$), *unemployed people* (n= 4) and *socially assisted people* ($n = 10$).

The results indicated that the number of children the patients had was statistically significantly different among different social categories, $F(4, 14.263) = 7.399$, $p = 0.002$. The mean number of children increased progressively from students (0.25 ± 0.46) to employees (1.29 ± 1.40), to pensioners (1.50 ± 0.97), to unemployed peo-

ple (1.50 ± 1.29), to socially assisted people (2.80 ± 2.15) groups. The Games-Howell post hoc analysis revealed that the increase in the number of children from students to employees was statistically significant (-1.03, 95% CI (-1.72 to -0.36)), (p = 0.001), the increase from students to pensioners was statistically significant (-1.25, 95% CI (-2.34 to -0.16)), (p = 0.022), and the increase from students to socially assisted people was statistically significant (-2.55, 95% CI (-4.85 to -0.25)), (p = 0.029), but no other group differences were identified. The diagnosis of fillings was statistically significant across various income levels, $F(4, 98) = 4.875$, $p < 0.001$. The rates increased from the income range of 5,000-7,000 RON (n=2)(1.00 ± 0.00), to the income range of 3,000-5,000 RON (n=15) (1.40 ± 0.50), to the income range of 1,500-3,000 RON (n = 48)(1.52 ± 0.65), to the income range of 500-1500 RON (n = 22)(1.82 ± 0.66), and finally to the under 500 RON income group (n = 16)(2.19 ± 0.65). Tukey post hoc analysis indicated that the increase from the under 500 RON group to the 1,500-3,000 RON income group (0.66, 95% CI (0.16 to 1.17)), (p = 0.004), as well as the increase from the under 500 RON group to the 3,000-5,000 RON income group were statistically significant (0.78, 95% CI (0.16 to 1.42)), (p = 0.007), while no other group differences were statistically significant.

A Pearson's correlation was conducted to assess the relationship between age and the degree of satisfaction regarding dental health. The results indicated a statistically significant negative correlation between these variables (r = -0.19, p = 0.04), suggesting that as participants aged, their satisfaction with dental health decreased. Additionally, age correlated positively with the diagnosis of gingivitis (r = 0.19, p = 0.04), in the sense that the incidence of gingivitis increases with age.

We identified that there were strong negative correlations between the level of education and the diagnosis of dental fillings (r = -0.38, p < 0.001), and respectively, between the income and the diagnosis of fillings (r = -0.39, p < 0.001). This indicated that higher levels of education and standards of living were associated with a lower frequency of this diagnosis. Additionally, the level of education correlated positively with income (r = 0.46, p < 0.001), in the sense that the higher the level of education, the higher the standard of living. The results proved negative correlations between the number of children and the number of packs of cigarettes consumed per day (r = -0.40, p = 0.008), as well as between the number of children and the prosthetic works that patients had (r = -0.37, p < 0.001). Thus, the more children the patients had, the less they smoked, and the fewer prosthetic works they had. The number of packs of cigarettes smoked per day correlated positively with dental pain (r = 0.35, p = 0.03), indicating that increased smoking leads to more pain. We identified a positive correlation between the pain felt by the patients and dental cavities (r = 0.224, p = 0.02), in the sense that more cavities result in higher pain levels. We identified a negative correlation between the frequency of visits to the dentist and periodontal pain (r = -0.26, p = 0.04), meaning that the more often patients visited the dentist, the less periodontal pain they experienced. Additionally, stress levels correlated negatively with dental pain (r = -0.35, p = 0.001), higher stress resulted in less dental pain. The results showed a strong positive correlation between the level of satisfaction regarding dental health and oral hygiene (r = 0.34, p < 0.001). Patients who took care of their teeth better were more satisfied with their dental

health. Additionally, dental health satisfaction correlated negatively with gingival bleeding ($r = -0.03$, $p = 0.029$), meaning that the more bleeding patients had, the less satisfied they were with their dental health.

DISCUSSION

Our results cover an important gap regarding the profile of patients in the emergency units in Oradea, detailing their sociodemographic characteristics and oral health-related behaviors. Most of the studies have also identified that women typically seek dental assistance in emergency units, indicating a delay in receiving dental care. However, few studies have shown that men are more likely to visit public emergency dental units. For example, Matsumoto *et al.* (2017) (9) analyzed the profile of Brazilian patients who accessed the public dental emergency units, finding that usually the patients were males, aged 30-52, with an elementary school level of education, with only one previous consultation in public dental units. Ottaviani *et al.* (2013) (10) found that male patients were more frequent beneficiaries of Italian public dental emergency services, while Verma and Chambers (2014) observed that in Australia, usually the patients were males younger than 30 years old (11). Our study found that nearly 75% of patients declared that they sought dental appointments only when necessary, while less than 20% had periodic checkups. These results are in congruency with literature, such as a study conducted by Schroeder *et al.* (2024) which indicates that lacking a regular dentist leads to higher emergency dental visits (12).

The results indicated negative correlations between the number of children and the number of packs of cigarettes consumed per day. Our study is in congruency with others identified in scientific literature. For example, Lippet (2021) (13) observed that parents, especially mothers, smoke less when having children, which improves children's oral health. Mahabee-Gittens *et al.* (2022) found that children aged 1-11 years old with less exposure to tobacco had fewer carries and less chronic difficulty with one or more oral health problems (14). Leroy *et al.* (2011) identified that previous exposure to tobacco was significantly associated with gingivitis in 5-year-old children (15). A recent meta-analysis showed a strong correlation between passive smoking and the increased prevalence of dental caries in children. Environmental tobacco smoke exposure and dental caries risk were influenced by factors such as low parental education, low socioeconomic status, poor dietary habits, low oral hygiene, and gender (Clemention *et al.*, 2025) (16).

We identified that approximately one-third of patients brushed their teeth either in the morning or at night, with morning brushing being more common than evening brushing. Teeth brushing is one of the most common behaviors that maintain oral health. Individuals from low socioeconomic (SES) backgrounds often brush less regularly (Raison *et al.*, 2021) (17). The study by Hwa-Young Lee *et al.* (2023) indicated that patients under the age of 30 years were more likely to brush after lunch, while those aged 40-79 were found to brush their teeth after dinner (18). Additionally, depending on the professional category, people engaged in services, as well as students, housewives, or unemployed people were less likely to brush their teeth after lunch compared to office workers.

Strengths and limitations of the study. The current research is important because it provides important statistical data about the environment of emergency dentistry, outlining a profile of the patients who access

public emergency medical services. These results are generalizable to the area population studied and useful for preventive campaigns. One limitation of the study is determined by the period in which the research took place, i.e., after the period of restrictions imposed by the COVID-19 pandemic, when access to dental interventions was carried out only for patients in critical dental situations and when routine checkups were avoided. It is very possible that the patients' oral health deteriorated because of these restrictions to accessing dental medical services and conventional treatment. This situation was very clearly presented by Sycinska-Dziarnowska and Paradowska-Stankiewicz (2020) (19) who, in their study, showed that during the period of restrictions imposed by the pandemic, the search for the word "toothache" had an increasing trend in all European countries and access to simple dental services was extremely limited (Nijakowski *et al.*, 2021) (20). Research conducted by Peloso *et al.* (2020) also identified that the level of anxiety among patients needing dentistry interventions was higher during pandemics (21). Patients undergoing dental treatment and orthodontics were more willing to attend appointments and were more concerned about an increase in treatment duration or expenses. The second limitation of the study is determined by the fact that the research was conducted in a single-center emergency unit, so the results should be interpreted in relationship with the socio-demographic and economic factors related to this geographic area. The third limitation of the study is caused by the number of socio-demographic factors that can force patients to access oral health services. An example would be the distance between their home and a dental clinic. A fourth limitation of the research is related to the lack of information about the profession or the level of health literacy (the latter being considered, implicitly, in this study, as being related to the patient's number of years of schooling). Finally, the medical condition-experiencing significant pain-could be also a limitation of the study, because maybe this category of patients chose not to answer the questionnaire because of their physical discomfort.

CONCLUSIONS

To prevent dental emergency problems and shape health policies in dentistry, it is essential to identify the profiles of patients seeking assistance in public dental emergency units. The results are valuable for health policymakers, as well as those responsible for health education, since health education and prevention play an important role in enhancing the quality of life in general. Given that the profile of the patients proves that most of the beneficiaries do not have more than a high-school level of instruction, it is essential to consider new strategies for delivering information through elementary school-level curricula.

INCOME, EDUCATION, AND BARRIERS TO DENTAL CARE ACCESS IN RURAL COMMUNITIES. A CROSS-SECTIONAL STUDY (Abstract): Access to dental services in rural areas is often limited by socio-economic and structural barriers, contributing to a high prevalence of dental caries and persistent oral health inequalities. **Aim:** This study aimed to assess access to dental services in a rural population and to analyze the associations between socio-economic factors, perceived barriers to care, and oral health status, measured using the DMFT index. **Materials and methods**: A cross-sectional observational study was conducted in 2025 among 72 adults living in rural areas of Bacău County, Romania. Participants underwent a standardized dental examination based on ICDAS criteria, and caries experience was assessed using the DMFT index. A structured questionnaire collected socio-demographic data and evaluated perceived financial, educational, and geographic barriers to dental care using a five-point Likert scale. **Results**: A very high prevalence of dental caries was identified, with DMFT values ranging from 0 to 25. Only 1.39% of participants were caries-free, while 22.22% presented DMFT ≥ 13. Higher DMFT scores were significantly associated with lower educational level ($r = -0.342$, $p = 0.003$), perceived financial constraints, and the perception that household income influences dental attendance ($r = 0.260$, $p = 0.027$). Geographic barriers also contributed, as perceived distance to the dental office was positively correlated with DMFT ($r = 0.340$, $p = 0.003$). Financial barriers were strongly interrelated and linked to delayed care and emergency-only visits ($p < 0.001$). Lower educational attainment was further associated with reduced understanding of medical advice and limited access to preventive information. **Conclusions:** Oral health disparities in rural populations are driven by interconnected socio-economic, educational, and geographic factors, underscoring the need for targeted preventive strategies, improved rural dental infrastructure, and enhanced public support. **Keywords:** RURAL POPULATION; DENTAL CARIES; ACCESS TO DENTAL CARE.

INTRODUCTION

Access to dental services in rural areas is significantly affected by household income levels. Evidence shows that individuals with low income and without dental insurance access dental care less frequently, particularly preventive services, which increases the risk of complications (1). In Romania, regional economic studies indicate a significant association between income level and the frequency of dental visits, with higher-income individuals being more engaged in preventive care and regular treatments (2). Consequently, lim-

ited financial resources in rural settings lead to a reliance on emergency treatments and delays in necessary oral healthcare.

Another essential factor is educational level and health literacy. Rural populations generally have lower levels of formal education and limited knowledge regarding oral hygiene, which negatively influences preventive attitudes. For example, a study conducted in Romania showed that only 38.8% of 12-year-old children in rural areas brush their teeth twice daily, and 11.2% have never attended a dental check-up (3). At the international level, an analysis of data from 27 countries confirmed that low educational attainment and reduced income are major predictors of infrequent dental visits and untreated oral health problems (4).

Deficient medical infrastructure and the unequal distribution of dental professionals represent additional major barriers. In the United States, more than 4,600 rural areas are classified as Dental Health Professional Shortage Areas, reflecting a chronic lack of specialized dental personnel in these regions (5). In Romania, although the overall number of dentists is relatively high, most practice in urban and private settings, while rural areas remain underserved and face difficulties in accessing care through the public system (6). This situation forces rural patients to travel long distances for dental treatment, resulting in increased time and financial costs and discouraging the utilization of dental services. Therefore, the aim of this study is to identify and analyze the socio-economic factors influencing access to dental services among the rural population, with particular emphasis on the roles of income level, education, and available healthcare infrastructure. The study seeks to highlight the main barriers contributing to inequalities in oral healthcare utilization and to propose potential intervention strategies to reduce these disparities.

The aim of the study was to assess access to dental services and to analyze associated socio- economic factors, based on clinical data and responses to a standardized questionnaire.

The study population consisted of adults aged 18 years and older who were permanent residents of rural localities in Bacău County. Participants were selected using simple random sampling, in accordance with predefined eligibility criteria, including provision of informed consent and the absence of severe systemic diseases.

For the clinical component, all participants underwent a standardized dental examination performed according to the criteria of the International Caries Detection and Assessment System (ICDAS), which was used to identify and record carious lesions (7). Caries experience was quantified using the DMFT index (Decayed, Missing, and Filled Teeth), in line with World Health Organization recommendations (8). All clinical assessments were performed in a dental clinic by a calibrated examiner.

In parallel, participants completed a structured questionnaire addressing access to dental care. The questionnaire included demographic and socio-economic variables (age, sex, educational level, occupational status, and monthly household income), as well as 15 items assessed on a five-point Likert scale (1 = strongly disagree to 5 = strongly agree). These items explored perceived barriers to accessing dental services, the influence of economic, educational, and geographic factors, and overall satisfaction with available dental care.

MATERIALS AND METHODS

This cross-sectional study was conducted as a descriptive, observational investigation between January and April 2025 among the adult population living in rural areas of Bacău County, Romania.

Collected data were processed and statistically analyzed using *SPSS software version 26.0*. Descriptive statistics included frequencies, means, and standard deviations for socio-demographic variables, questionnaire responses, the DMFT index, and ICDAS scores.

Correlation analyses

(Pearson or Spearman, depending on data distribution) were applied to examine associations between socio-economic variables (income, educational level, occupational status), caries experience (DMFT), and perceived access to dental services. Group differences were assessed using Student's *t* test or ANOVA for continuous variables (DMFT), and chi- square tests for categorical variables (perception frequencies across educational levels). Statistical significance was set at $p < 0.05$.

RESULTS

The study sample included 72 participants from rural areas, with a mean age of 39.13 ± 13.16 years. Sex distribution was balanced (52.78% men and 47.22% women). Most respondents had completed upper secondary education (62.50%), followed by those with post-secondary or higher education (31.94%), indicating a relatively high level of literacy. Regarding occupational status, 69.44% were employed, while the remainder belonged to socio- economically vulnerable groups. Monthly household income was predominantly between 2001-3000 RON (43.06%) or above 3000 RON (31.94%). With respect to dental care financing, 56.94% of participants benefited from reimbursed dental services (tab.1).

TABLE I.

Socio-demographic and economic characteristics of the study sample

Characteristic	Category	n	%
Area of residence	Rural	72	100
Age (years)	Mean ± SD	-	39.13 ± 13.16
	Dominant age groups	-	25-35; 45-50
Sex	Male	38	52.78
	Female	34	47.22
Education level	No formal education	1	1.39
	Lower secondary (gymnasium)	3	4.17
	Upper secondary (high school)	45	62.50
	Post-secondary / higher education	23	31.94
Occupational status	Employed	50	69.44
	Unemployed	10	13.89
	Retired	5	6.94
	Student	7	9.72
Monthly household income	< 1000 RON	5	6.94
	1001-2000 RON	13	18.06
	2001-3000 RON	31	43.06
	> 3000 RON	23	31.94
Payment method for dental treatments	Reimbursed by the National Health Insurance (NHI)	41	56.94
	Out-of-pocket payment	31	43.06

The analysis of DMFT scores indicates an extensive caries experience among participants, with values ranging from 0 to

25. The most frequent scores were 9 (13.89%), 6 and 12 (12.50% each), while only 1.39% of respondents presented no caries experience (DMFT = 0), highlighting a very high prevalence of the condition. Additionally, 22.22% of participants recorded DMFT values ≥ 13, suggesting advanced oral impairment and underscoring the need for analyses correlated with socioeconomic factors, as well as for preventive interventions in rural settings.

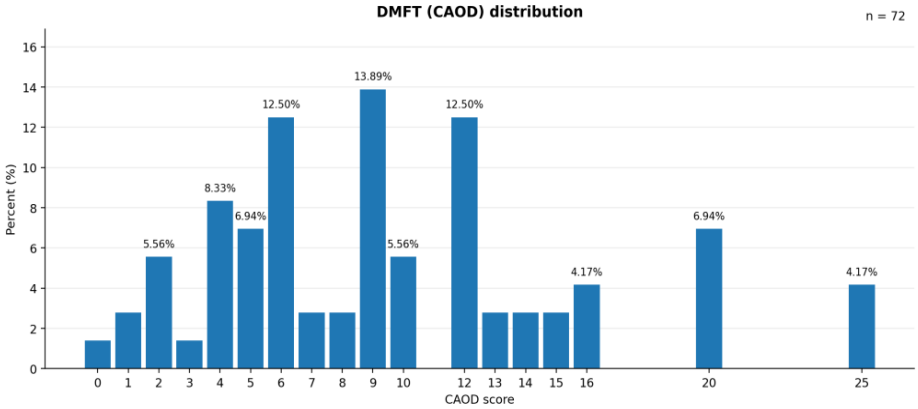

Fig. 1. Distribution of participants according to DMFT values perceptions regarding access to dental services and perceived barriers analysis

Socioeconomic factors further shaped access to care, as 86.11% of participants acknowledged that household income influences the decision to seek dental treatment. More than half of respondents (59.73%) perceived free or reimbursed dental services as insufficient, indicating limited public financial support. Preventive care was also considered inadequate: 56.94% believed that dental prevention is not a community priority, while 59.72% reported a lack of oral health information campaigns. Educational level influenced communication with healthcare providers for 59.73% of participants, emphasizing the role of health literacy. In contrast, waiting time was not viewed as a major barrier, with only 13.89% considering it problematic. Notably, all respondents (100%) agreed that greater investment by authorities in rural dental infrastructure is necessary, underscoring the need for systemic interventions to improve oral healthcare access in rural populations (tab. II).

TABLE II.

Participants' perceptions regarding access to dental services and perceived barriers (questionnaire)

Assessed statement	Strongly disagree (%)	Disagree (%)	Neutral (%)	Agree (%)	Strongly agree (%)
Distance to the dental office influences the decision to seek dental care	4.17	5.56	1.39	41.67	47.22
Cost of dental treatments represents a barrier	-	4.17	16.67	58.33	20.83

Assessed statement	Strongly disagree (%)	Disagree (%)	Neutral (%)	Agree (%)	Strongly agree (%)
Lack of adequate transportation hinders access to dental services	-	26.39	30.56	37.50	1.39
Household income influences the decision to visit the dentist	-	4.17	9.72	56.94	29.17
Information on dental prevention is insufficient in the community	-	19.44	20.83	48.61	9.72

Correlations between socio-economic variables and clinical scores

Correlation analysis revealed several statistically significant relationships between the variables examined. Monthly household income was positively and significantly correlated with education level ($r = 0.336$; $p = 0.004$) and negatively correlated with occupational status ($r = -0.464$; $p < 0.001$), indicating that individuals with higher incomes generally have higher educational attainment and are more frequently employed, whereas lower income levels are associated with more vulnerable occupational statuses. Education level showed a significant negative correlation with the DMFT score ($r = -0.342$; $p = 0.003$), suggesting that higher educational attainment is associated with a lower caries experience. In contrast, no significant correlations were observed between the DMFT score and occupational status ($r = -0.080$; $p = 0.502$) or monthly household income ($r = -0.043$; $p = 0.721$) (fig. 2).

The statistical analysis highlighted two significant relationships between the DMFT score and perceived barriers to accessing dental services. A positive correlation was observed between DMFT and the perception that distance to the dental office influences the decision to seek care ($r = 0.340$, $p = 0.003$), indicating that individuals who perceive distance as a barrier tend to have poorer oral health status. In contrast, the perception that access to dental services is more difficult in rural areas than

in urban settings was negatively correlated with the DMFT score ($r = -0.322$, $p = 0.006$), possibly suggesting that individuals with lower DMFT scores are more aware of access inequalities. Other variables, such as lack of transportation or waiting time for appointments, did not show significant correlations (fig. 3).

The relationship between caries experience and perceived barriers to dental care was explored using Pearson correlation analysis. The results revealed a significant positive association between the DMFT score and the perception that household income influences dental attendance ($r = 0.260$, $p = 0.027$). In contrast, no significant correlations were observed between DMFT and other cost-related variables, despite the strong intercorrelations among financial barriers themselves ($p < 0.001$). Furthermore, DMFT showed a positive correlation with the perception that educational level affects the understanding of medical advice ($r = 0.389$, $p = 0.001$), indicating a higher caries experience among individuals with lower educational attainment. Although DMFT was not directly associated with other prevention- related perceptions, these factors were significantly interrelated, emphasizing the central role of education in oral health outcomes and preventive behaviors (figs. 4, 5).

To better understand the determinants of access to dental services, Pearson correlation analysis was conducted to examine the role of educational and economic factors. The results showed that lower educational level was significantly associated with perceiving distance to the dental office as a barrier ($r = -0.308$, $p = 0.009$) and with reporting longer waiting times ($r = -0.392$, $p = 0.001$). In addition, lack of transportation was significantly linked to distance, waiting time, and difficulties in accessing dental care in rural areas ($p \leq 0.032$). The negative correlation between rural access difficulties and distance ($r = -0.236$, $p = 0.046$) suggests that barriers in rural settings extend beyond simple geographic proximity (fig. 6).

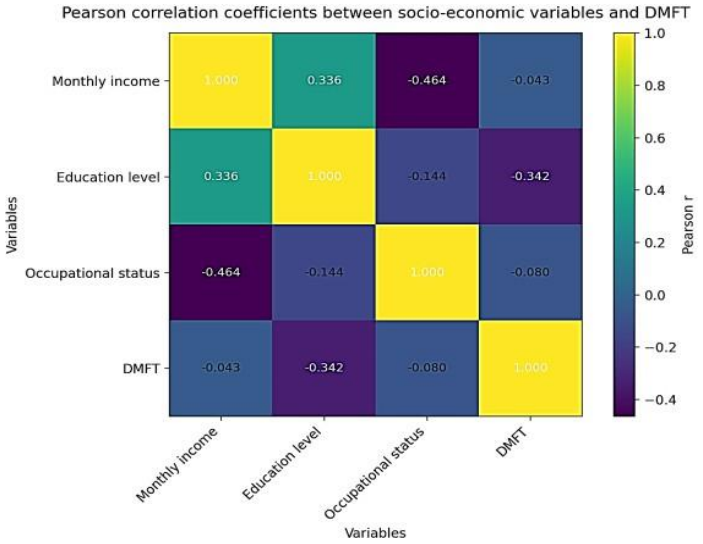

Fig. 2. Correlations between DMFT and monthly income, occupational status, and education level

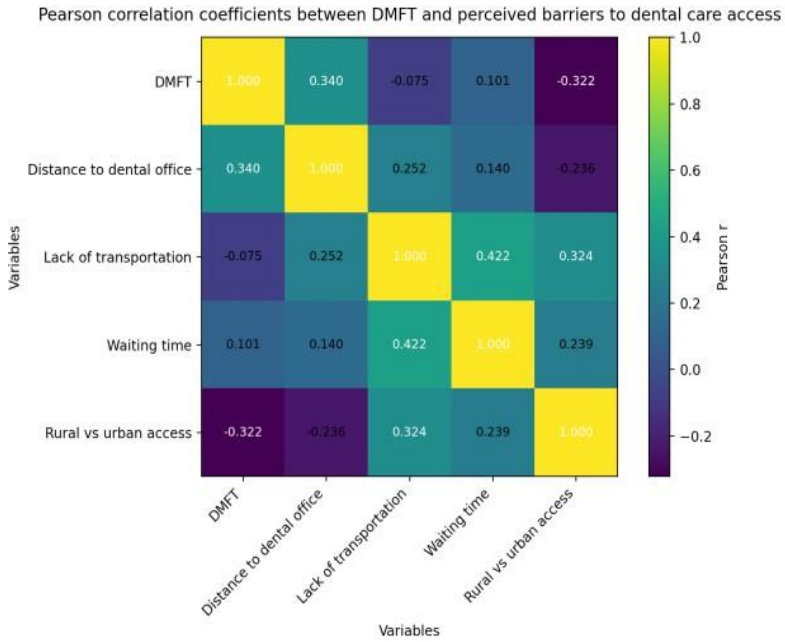

Fig. 3. Correlations between DMFT and perceived barriers to access to dental services

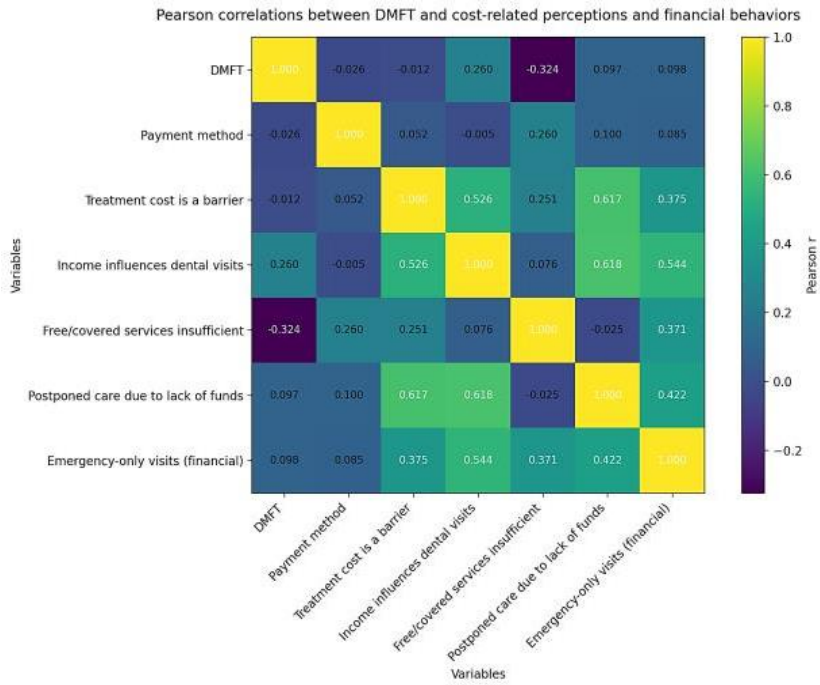

Fig. 4. Pearson correlations between the DMFT score and cost-related perceptions and financial behaviors associated with access to dental care

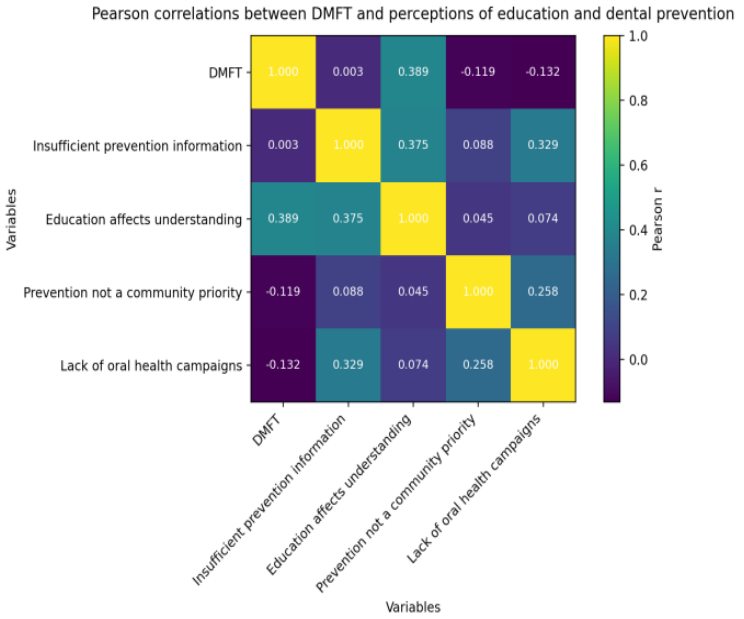

Fig. 5. Pearson correlations between the DMFT score and perceptions related to education and dental prevention

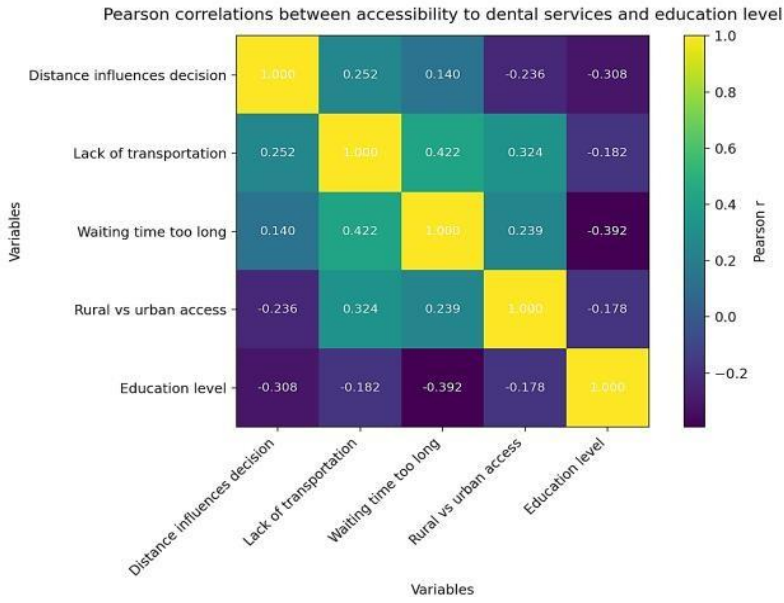

Fig. 6. Pearson correlations between accessibility to dental services and educational level

Economic constraints also played a major role: the perception that household income influences dental attendance was strongly associated with high treatment

costs (r = 0.526), postponement of dental care (r = 0.618), and reliance on emergency-only visits (r = 0.544). Conversely, higher educational attainment was negatively associated with these financial barriers, indicating a protective effect of education (fig. 7). Overall, these findings emphasize the combined and interdependent impact of education and income on access to dental care.

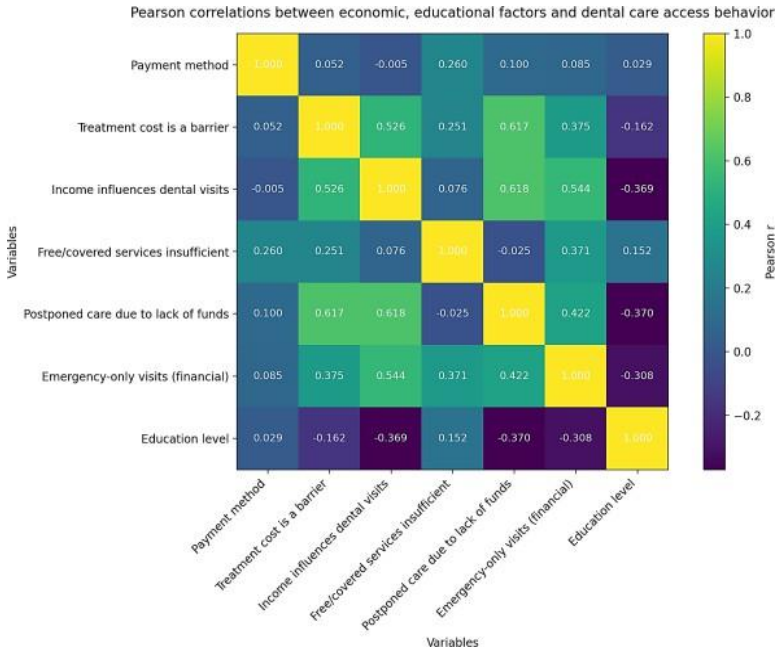

Fig. 7. Pearson correlations between economic and educational factors and dental care-seeking behavior

Lower educational level was significantly associated with difficulties in understanding dentists' advice (r = −0.557, p < 0.001) and with the perceived lack of oral health information campaigns (r = −0.268, p = 0.023), while insufficient preventive information was linked to both limited understanding and absence of campaigns (p ≤ 0.005) (fig. 8). Lower household income was associated with transportation barriers (r = −0.255, p = 0.031), rural access difficulties (r= −0.290, p = 0.014), and especially longer waiting times for appointments (r = −0.592, p < 0.001), underscoring the combined impact of education, income, and infrastructure on access to dental care (fig. 9).

Correlation analysis of socio-economic factors revealed a significant influence of income and education on dental care- seeking behavior. Household income was strongly associated with perceived financial barriers, including the decision to seek dental care (r = 0.526, p < 0.001), postponement of treatments (r = 0.618, p < 0.001), and reliance on emergency-only visits (r = 0.544, p < 0.001), while treatment costs were also perceived as a major obstacle (r = 0.617, p < 0.001). Education level was negatively correlated with these barriers (postponement of care: r =−0.370, p = 0.001), indicating greater vulnerability

among less educated individuals. Additionally, lower income was associated with the perception that dental prevention is not a community priority ($r = -0.509$, $p < 0.001$) and showed borderline negative associations with insufficient preventive information and lack of campaigns. Difficulties in understanding medical advice were significantly related to perceived educational level ($r = 0.375$, $p = 0.001$), highlighting the role of health literacy in oral health prevention (figs. 10, 11).

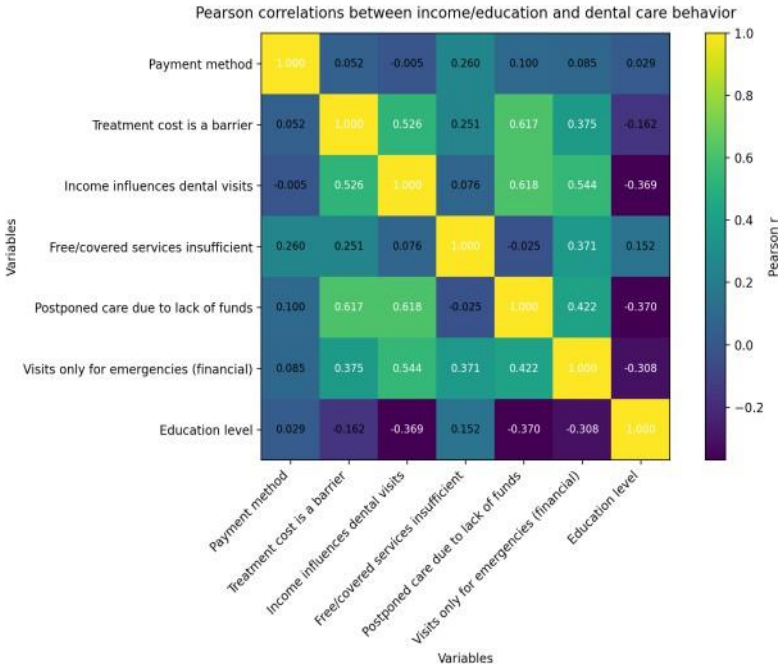

Fig. 10. Pearson correlations between income level and education in relation to dental care- seeking behavior

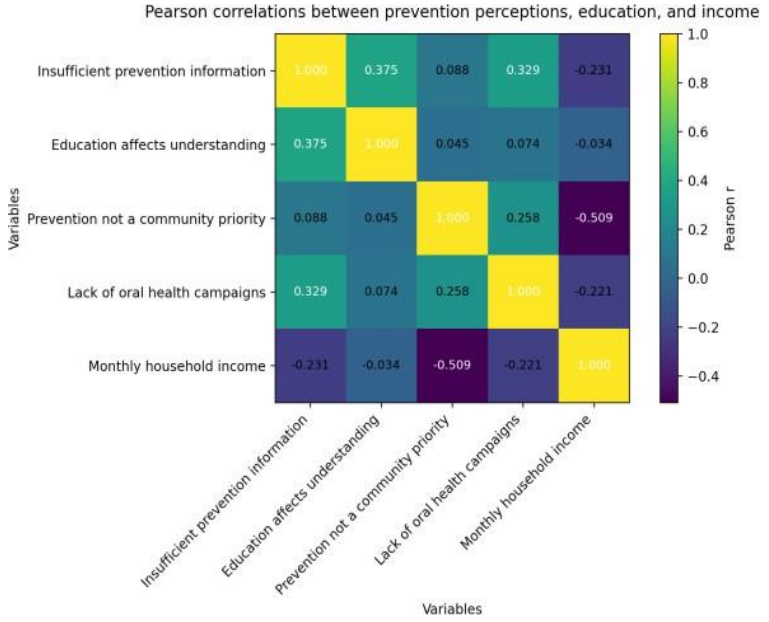

Fig. 11. Pearson correlations between monthly household income and perceptions of dental prevention

DISCUSSION

The present study provides evidence that access to dental services and oral health status in rural populations are strongly influenced by socio-economic and educational determinants. The high prevalence of dental caries observed in the study sample, reflected by elevated DMFT values, is consistent with previous research indicating that rural and socio- economically disadvantaged populations experience a disproportionate burden of oral disease (8, 9).

Educational level emerged as a key protective factor, showing a significant negative association with DMFT scores. Participants with higher educational attainment exhibited lower caries experience, likely due to improved oral health literacy, greater awareness of preventive practices, and more regular utilization of dental services. These findings are in line with international studies demonstrating that education strongly influences oral health behaviors and outcomes (10, 11).

Economic constraints also played a central role in shaping access to dental care. Although monthly household income was not directly correlated with DMFT scores, the perception that income influences the decision to seek dental care was significantly associated with higher caries experience. Financial barriers-including high treatment costs, postponement of care, and reliance on emergency-only visits- were strongly interrelated, suggesting a cumulative and systemic effect on dental care-seeking behavior. Similar patterns have been reported in both European and global studies, where cost-related barriers were identified as major determinants of delayed or avoided dental care (1, 13).

Geographic accessibility further compounded these inequalities. Perceived distance to dental clinics and lack of transportation were associated with poorer oral health outcomes, highlighting structural barriers faced by rural populations. These results align with evidence showing that rural residence is associated with reduced availability of dental professionals and increased travel distance, negatively affecting service utilization (14, 15).

Finally, the widespread perception of insufficient preventive information and lack of community-based oral health campaigns underscores the need for targeted public health interventions. Health promotion strategies focusing on oral health education, combined with improved access to publicly funded dental services, are essential to reduce inequalities and improve oral health outcomes in rural communities (16, 17).

CONCLUSIONS

The findings of this study demonstrate that oral health status in rural populations is strongly influenced by socio- economic and educational factors. Higher educational attainment was consistently associated with lower DMFT (CAOD) scores, while lower income, perceived financial barriers, and delayed care were linked to increased caries experience. Geographic accessibility, particularly perceived distance and lack of transportation, further contributed to poorer oral health outcomes. Limited health literacy and insufficient community-based preventive information were also associated with higher DMFT scores, underscoring the importance of education and preventive awareness. These results highlight a cycle of socio-economic disadvantage affecting access to dental care and oral health and support the need for targeted public investment in rural dental infrastructure, preventive programs, and health education to reduce oral health inequalities.

MEANING IN LIFE AS A MEDIATOR BETWEEN CONSERVATISM AND QUALITY OF LIFE AMONG OLDER ADULTS: A CROSS-SECTIONAL STUDY (Abstract): Population aging presents growing challenges for maintaining quality of life in later adulthood. Conservative personal values and existential meaning are both associated with well-being in older adults, yet their functional relationship remains unclear. **Aim:** The present study aimed to investigate the mediating mechanism through which the presence of meaning in life influences the relationship between value conservatism and quality of life in older adults. **Materials and methods:** A sample of 210 participants (mean age = 74.5 years, SD = 6.24, 63.3% women) completed a battery of standardized questionnaires: the WHOQOL-OLD to assess quality of life, the Meaning in Life Questionnaire to assess existential meaning, and the Schwartz Value Survey to measure personal values. Mediation analysis was conducted using the *PROCESS macro* for *SPSS version 28* (Model 4), applying a bootstrap procedure with 5,000 resamples. **Results:** The mediation analysis indicated that the presence of meaning in life partially mediated the relationship between conservatism and quality of life. Conservatism significantly predicted the presence of meaning ($b = 0.072$, $p = .017$), and the presence of meaning significantly predicted quality of life ($b = 0.129$, $p = .005$), even after controlling for conservatism. The indirect effect of conservatism on quality of life through the presence of meaning was significant ($b = 0.0093$; 95% CI [0.001, 0.024]), accounting for approximately 13.8% of the total effect. **Conclusions:** The findings demonstrate that conservative values enhance quality of life in older adults both directly and indirectly by strengthening existential meaning, providing empirical support for the development of integrated interventions focused on cultivating meaning and reinforcing stable values in the service of successful aging. **Keywords:** PRESENCE OF MEANING IN LIFE; VALUE CONSERVATISM; QUALITY OF LIFE; OLDER ADULTS; MEDIATION.

INTRODUCTION

Population aging represents one of the most significant demographic transformations of the twenty-first century. The central challenge of contemporary research is to ensure high quality of life in older age through the interaction between biological resources, social context, and psychological mechanisms of adaptation (1). Quality of life is conceptualized as a multidimensional construct encompassing physical functioning, emotional well-being, social relationships, autonomy, and existential meaning (2, 3), with psychological and existential factors becoming increasingly important in advanced age (4).

Personal values represent stable motivational principles that guide behavior across the lifespan. Older adults increasingly prioritize conservation values-tradition, security, and conformity-as an adaptive strategy for maintaining identity coherence (5, 6). In parallel, meaning in life-defined as the perception that one's existence is coherent, significant, and goal-directed (7)-is associated with lower depression, better cognitive functioning, and reduced mortality in later adulthood (8, 9).

Although values and meaning have been studied as independent predictors of quality of life, their functional relationship remains insufficiently clarified. The present study proposes that value conservatism influences quality of life both directly and indirectly through the cultivation of existential meaning, grounded in continuity theory (10) and existential frameworks emphasizing meaning as a core psychological resource in later adulthood.

MATERIALS AND METHODS

Participants. The sample consisted of 210 community-dwelling older adults (mean age = 74.5 years, SD = 6.24, range = 65-91 years; 63.3% women) recruited from urban and peri-urban areas in northeastern Romania. Inclusion criteria were: (a) age >= 65 years; (b) absence of severe cognitive impairment (MMSE score >= 24); (c) ability to provide informed consent; and (d) willingness to complete self-report questionnaires. Participants were recruited through community centers, senior clubs, and religious organizations using convenience and snowball sampling.

Measurements. *Quality of life* was assessed using the World Health Organization Quality of Life Instrument for Older Adults (WHOQOL-OLD; 3), a 24-item self-report questionnaire measuring six facets: sensory abilities, autonomy, past, present and future activities, social participation, death and dying, and intimacy. Items are rated on a 5-point Likert scale (1 = not at all; 5 = completely), with higher scores indicating better quality of life. The Romanian version has demonstrated good psychometric properties (Cronbach's alpha = .91 in the current sample).

Meaning in Life. Meaning in life was measured using the Meaning in Life Questionnaire (MLQ; 11), which comprises two 5-item subscales: Presence of Meaning and Search for Meaning. Items are rated on a 7-point Likert scale (1 = absolutely untrue; 7 = absolutely true). Only the Presence subscale was used in the current analyses. The Romanian version demonstrated excellent internal consistency (Cronbach's alpha = .87).

Personal Values. Personal values were assessed using the Schwartz Value Survey (SVS; 12), which measures ten basic values organized into four higher-order dimensions. For this study, we focused on the Conservation dimension, comprising three values: security, tradition, and conformity. Participants rated the importance of each value as a guiding principle in their life on a 9-point scale (-1 = opposed to my values; 7 = of supreme importance). A composite Conservation score was computed by averaging the three subscales (Cronbach's alpha = .76).

Procedure. The study protocol was approved by the Ethics Committee of Alexandru Ioan Cuza University. Data were collected between February and September 2024. Trained research assistants administered the questionnaires in individual sessions lasting approximately 75 minutes. Participants provided written informed consent and were assured of confidentiality and the right to withdraw at any time. All procedures were conducted in accordance with the Declaration of Helsinki.

Statistical analysis Descriptive statistics and bivariate correlations were computed using *SPSS version 28.0*. To test the hypothesized mediation model, we used the PROCESS macro for SPSS (Model 4; 13), with value conservatism as the independent variable, quality of life as the dependent variable, and presence of meaning in life as the mediator. The significance of the indirect effect was assessed using bias-corrected bootstrap confidence intervals based on 5,000 resamples. Statistical significance was set at alpha = .05, two-tailed.

RESULTS

Descriptive statistics and correlations. Table I presents descriptive statistics and bivariate correlations among study variables. Value conservatism was positively correlated with both presence of meaning in life ($r = .164$, $p = .017$) and quality of life ($r = .232$, $p < .001$). Presence of meaning was also positively associated with quality of life ($r = .220$, $p < .001$). All distributions approximated normality (Skewness < |2.0|, Kurtosis < |2.0|).

TABLE I.

Means, standard deviations, and correlations among study variables

Variable	M	SD	1	2
1. Overall quality of life	3.28	0.43	---	---
2. Presence of meaning in life	3.61	0.64	.22***	---
3. Conservatism values	6.39	1.47	.23***	.16*

M = mean; SD = standard deviation. N = 210. *p < .05. **p < .01. ***p < .001 (two-tailed).

Mediation analysis. Table II presents the results of the mediation analysis. Value conservatism significantly predicted presence of meaning in life (path a: b = 0.072, SE = 0.03, t = 2.40, p = .017). Presence of meaning significantly predicted quality of life after controlling for conservatism (path b: b = 0.129, SE = 0.05, t = 2.86, p = .005). The direct effect of conservatism on quality of life remained significant after including the mediator (path c': b = 0.058, SE = 0.02, t = 2.93, p = .004).

TABLE II.

Mediation analysis examining the indirect effect of conservation values on quality of life via presence of meaning in life

Model	Outcome variable	Predictor	B	SE	t	p
1	Presence of meaning in life	Conservation values	0.07	0.03	2.40	.017
2	Quality of life	Presence of meaning	0.13	0.05	2.86	.005
2	Quality of life	Conservation values	0.06	0.02	2.93	.004
Direct effect (c')	Quality of life	Conservation values	0.06	0.02	2.93	.004
Indirect effect (a x b)	Quality of life	Conservation -> Meaning -> QoL	0.0093	0.006	---	---

N = 210. B = unstandardized regression coefficient; SE = standard error.
The indirect effect was significant, 95% bootstrap 5000, CI [0.001, 0.024]. Proportion mediated = 13.8%.

The mediation model is illustrated in first figure. The total effect of conservatism on quality of life was significant (c = 0.067, SE = 0.022, t = 3.05, p = .003). The indirect effect through presence of meaning was statistically significant (ab = 0.0093, SE = 0.0057, 95% CI [0.001, 0.024]), indicating partial mediation. The indirect effect accounted for approximately 13.8% of the total effect.

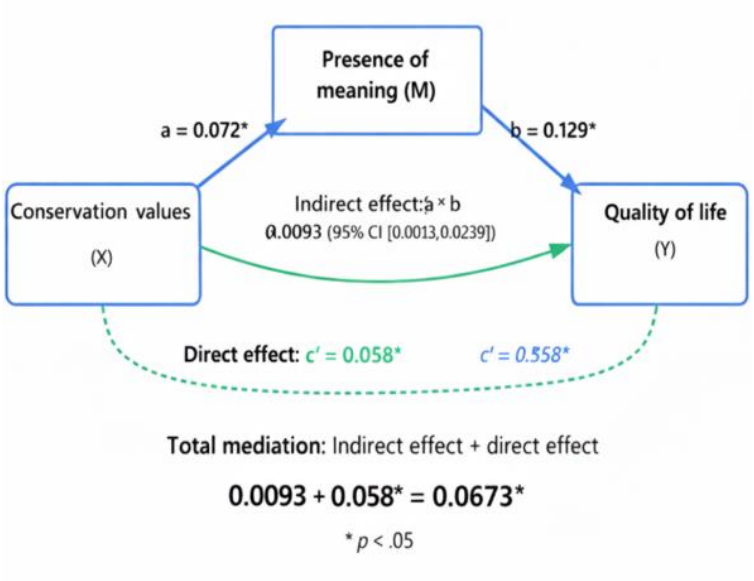

Fig. 1. Mediation model: the effect of conservation values on quality of life via presence of meaning in life

Legend for illustrations: X = independent variable; M = mediating variable; Y = dependent variable; a = 0.072* (path X → M); b = 0.129* (path M → Y); c' = 0.058* (direct path X → Y); Indirect effect: a × b = 0.0093. *p < .05

DISCUSSION

The present study examined the mediating role of presence of meaning in life in the relationship between value conservatism and quality of life among older adults. Results supported the hypothesized partial mediation model, indicating that conservative values promote quality of life both directly and indirectly through the enhancement of existential meaning.

Consistent with continuity theory (10) and socioemotional selectivity theory (14, 15), our results demonstrate that conservative values serve adaptive functions in later adulthood by providing psychological anchors amid biological and social transitions. The significant indirect effect through presence of meaning reveals that conservative values actively facilitate the construction and maintenance of existential meaning, which in turn enhances well-being. By anchoring individuals in biographical continuity and social belonging, conservative values provide interpretive frameworks through which life experienc-

es are organized into coherent narratives of purpose (16, 17).

From a practical standpoint, these findings suggest that interventions aimed at enhancing quality of life in older adults may benefit from incorporating components that strengthen both existential meaning and value clarity.

Reminiscence therapy, life review interventions, and narrative approaches that help older adults articulate their core values and connect them to life experiences may be particularly effective.

Limitations and future directions. Several limitations should be acknowledged. First, the cross-sectional design precludes causal inferences; longitudinal studies are needed to establish temporal precedence. Second, the sample was drawn from a culturally traditional context, which may limit generalizability. Third, reliance on self-report questionnaires raises concerns about common method variance. Future research should incorporate behavioral indicators and examine whether other value dimensions operate through different mediating mechanisms.

CONCLUSIONS

This study provides empirical support for the proposition that personal values influence quality of life in older adults through the cultivation of existential meaning. By demonstrating that conservative values enhance well-being both directly and indirectly via strengthened meaning in life, these findings advance understanding of the psychological mechanisms underlying successful aging and underscore the importance of integrating value-based and meaning-focused interventions in gerontological practice.

SOCIO-DEMOGRAPHIC CHARACTERISTICS, EDUCATIONAL MOTIVATION AND GEO-CULTURAL COMFORTABILITY RELATED TO THE PROCESS OF ADAPTATION OF FRESHMAN INTERNATIONAL STUDENTS IN A ROMANIAN UNIVERSITY (Abstract): Successfully integrating international students in a university is one of the main goal of an academic institution. **Aim:** To identify the characteristics of international students enrolled in first year of study. **Material and methods:** a number of 128 freshman international students from 23 countries were included in the research. The subjects had to complete a document with socio-demographic data and to answer to several items. Data was processed using IBM SPSS Statistics, version 23. **Results**: 67 men (52.37%) and 61 women (47.66%) with an age of 19.59 ± 2.21 were included in the research. More than half of international students are fluent in three languages. 58.73% of students' fathers and 67.97% of their mothers graduated from university. A number of 13 (N = 10.48%) declared that at least one of their parents is physician and almost half of them have at least one relative studying in the university. The levels of satisfaction with the relationship with colleagues, teachers and administrative staff are analyzed. **Conclusions**: International students have criteria for choosing their academic institutions. Universities and academic staff mast take into consideration their reasons used in choosing the institution and social, cultural, religious or daily life aspects must be supervised to help them become more integrated into the community. **Keywords**: INTERNATIONAL STUDENT, UNIVERSITY, MEDICAL STUDY, DISCRIMINATION, SATISFACTION.

Pressed by the high number of students from abroad who would like to study in another country, universities had to change over the years to meet internationals students' needs and to adjust their educational offer to satisfy their professional expectations.

Both our borders and culture become more accepting towards immigrants from all over the world, and less judgmental of people who are different. The educational system in our country has been subjected to a rise in the number of students of various cultures. With that in mind, the phenomenon of acculturation stress has also become more noticeable.

With the work of psychologists, such as

Berry and Rudmin (1) certain systems and scales have been effectively put together and improved throughout the last decade, thus helping analyze and quantify the level, prevalence and importance of various stressors. It is very important to identify more efficient means of helping international people, especially students, in dealing with the pressure of a new society.

The stress related to acculturation is the phenomenon experienced by individuals or groups, on a psychological and cultural level, during the adjustment to a foreign culture (2). Berry et all helped identify vital stressors arising from the adjustment period, as well as develop the idea of the 4 different coping strategies which have been confirmed to follow 3 main steps: 1. Contact period, 2. Conflict period and 3. Resolution period (3, 4).

International students, according to research, present common stressors such as cultural shock (5) along with conflicts and psychological issues that may occur throughout the adjusting timeframe. (6, 7, 8). Among main stressors are the following: language barrier, cultural aspects, religious facilities, relationship with family, social support and academic facilities.

The present study is a preliminary one and is part of a larger study focusing on international students in a medical university from North-Eastern Romania. The aim is to identify socio-demographic characteristics of international students and to evaluate their level of satisfaction of their relationship with administrative staff, colleagues and teachers. Also, the level of comfort with some aspects of their daily life are also regarded. In the university students are enrolled to accomplish their medical studies in one of the three study languages: Romanian, English and French. This study targets international students from the first year, focusing especially on those registered in English section (from a total of approximately 220 freshman students), but English speakers from French sections were also included in the research.

MATERIAL AND METHODS

The goal of the research

The aim of the research was to identify socio-demographic characteristics and factors related to the process of integration of international students enrolled in first year of study in "Grigore T. Popa" University of Medicine and Pharmacy of Iasi, Romania. The study presents some results from a larger research obtained by a grant competition organized by University of Medicine and Pharmacy Iasi, Romania and *Agence Universitaire pour la Francophonie* (AUF) in 2017 and approved by both institutions.

Participants

A number of 150 questionnaires were distributed among freshman students from Medical Faculty and Dental Medical Faculty, studying in French and English sections. Before the completion of data, students were informed about the purpose of the study and the use of data, with the respect of confidentiality of data. The questionnaire was distributed to students after they were questioned about their level of English language, because documents were formulated in English. Students were informed that the questionnaire was optional, and they could decline filling it in, with no consequences. In total, 145 questionnaires returned to the researchers and 128 of them (85.33%) were considered for the study. The exclusion criterion was: the questionnaires were not fully filled in or they were

delivered after the requested date.

Questionnaires

The questionnaires gathered information referring to the following aspects:

- socio-demographic characteristics a family-related data (age, sex, marital status, religion, nationality, country of origin, maternal language, the number of languages spoken fluently, the level of education of their parents, if one of the parents is a physician, the number of siblings, if their parents were speaking Romanian language, if they have relatives, friends or siblings enrolled in their institution of study),
- academic data (language of study, previous experience in other universities from Romania or abroad),
- information related to their choice regarding enrollment in Faculty of Medicine in Iasi and the country where they intend to work after graduation were also gathered.

Several items were formulated to identify their level of comfort related to their living in the University City. Answered for formulated on a Lickert-like scale from 1 to 5 (1 – *not comfortable*, 2 – *somewhat comfortable*, 3 – *comfortable*, 4 – *very comfortable*, 5 – *extremely comfortable*). The items referred to their comfort of communicating in English or Romanian, climate, transportation, food or relationship with neighbors in Iasi.

Also, some questions were formulated to identify their level of satisfaction with the administrative staff, colleagues or teachers. The answers were rated on a scale from 1 (*very unsatisfied*) to 10 (*very satisfied*).

Statistical analysis of data

The statistical analysis of data was done suing IBM *SPSS Statistics, version 23.0.*

RESULTS AND DISCUSSION

Socio-demographic and family data

A number of 67 men (52.37%) and 61 women (47.66%) from 23 countries were included in the research. They are studying in two faculties of the university: General Medicine (N = 110, 85.94%) and Dental Medicine (N = 18, 14.06%). The average age is M = 19.59 ± 2.21, range 17-30 years old. Approximately 82% of participants are aged between 18-20 years old.

The majority of them are studying in English language (N = 110, 85.94%) but also 18 students from French language section (14.06% of respondents) choose to answer to the questionnaires.

Most them are single (N = 103, 81.10%), a small part sustained that they are in relationship (N = 21, 16.54%) and three of them are married.

Questioned students are from 23 nationalities from all over the world, but the highest rates are Israeli (61.60%), French (12.80%) and Greek (8%). The other self-declared nationalities are: German, Canadian, Benin, Irish, Lebanese, Polish, Cypriot, American, Morocco, Vietnam, Palestinian, Romanian, Tunisian, Turkish, Finnish, British, Italian, Philippine, Zimbabwean. Three students have double-nationality.

Most students included in the research are Muslims (N = 85, 66.4%), 26 (20.3%) are Christian-Orthodox, 3 are Protestants, 2 are Catholics and 1 students is Hindu.

More than half of freshman international students are fluently speaking three languages (N = 64, 50.39%), almost a quarter of them are speaking four languages (N = 30, 23.62%) and 26 (20.47%) are speaking two languages.

Twelve students (9.52%) have Romanian origins. They were also asked if their parents speak Romanian. Fifteen of them

declared that their mothers speak Romanian and 15 of them that their fathers speak this language.

Regarding the level of education of their parents, 74 (58.73%) of fathers are have a university degree and 87 (67.97%) of their mothers graduated from university. A number of 13 (N = 10.48%) declared that at least one of their parents is physician. Only 5 of students (4.03%) are singleton. 21 (16.94%) are having one sibling, 39 (31.45%) are having 2 siblings, 28 (22.58%) are having 3 siblings and 16 (12.90%) are having 4 siblings. A total of 12.12% of international students are coming from a family with more than 6 children.

Almost half of them are having at least one relative studying in the university (N = 60, 48%).

Academic data and information related to the educational/professional choices

A number of 36 students (28.57%) declared that they were previously enrolled in other universities, and among the most mentioned countries is France (41.18%), Israel, United Kingdom and Greece (with 5.88% each).

The main reasons for choosing to study in this university are presented in tab. 1. Among the answers related to the prestige of the university were the following: it is a good university, it offers a lot of practice, it is a European university, it was proposed by friends and former students from all over the world). Also, students mentioned their trust in the academic offer (they have or had friends enrolled in the university or they know about the country or the university from their relatives or friends). Regarding personal advantages, international students mentioned they close distance to their countries of origin that they speak the language or that studies are most cheap comparing to other universities.

TABLE I
The main reasons to choose studying in the University of Iasi

The main reason for choosing to study in Iasi	N (%)
The university prestige	52 (40.65%)
Trustful in academic offer and city life	36 (28.12%)
Personal advantages	27 (21.09%)

Life in the University City

Students were asked to answer to some questions related to their life in the university city. 63 international students (52.07%) share am apartment with a friend or a colleague. Because a large part of the students declared their religion and this aspect is an important factor for adjusting adequately to the new life as student, subjects were asked about how they succeed in being a part of their religious community. A total of 59 of them (46.1%) declared that they can practice their religion in mosque (22%), churches (22%) or at home (56%).

Also, they had to answer to five items trying to identify their level of comfort during their first months in at the faculty, related to the following aspects: climate, transportation, neighbors, communicating with the owner of the apartment or with food. The temperature and food seem to be the most uncomfortable aspects that students must deal with. The distribution of their answers is presented in Table II.

Almost a quarter of subjects (N = 29, 22.7%) declared that they feel discriminated in their first few months as student: 4.7% by neighbors, 4.7% by teachers, 6.3% by people during city transportation, 6.3% by colleagues and 10.2% by citizens.

TABLE II

The distribution of answers to items regarding students' life in the University City (N, %)

How comfortable are you with...	not comfortable	somewhat comfortable	comfortable	very comfortable	extremely comfortable	M ± st dev
...the climate in Romania?	20 (15.6%)	35 (27.3%)	45 (35.2%)	23 (18%)	5 (3.9%)	2.67±1.07
...the transportation in the city?	5 (3.9%)	41 (32%)	51 (39.8%)	26 (20.3%)	5 (3.9%)	2.88±0.91
... your neighbors?	16 (12.5%)	24 (18.8%)	52 (40.6%)	21 (16.4%)	14 (10.9%)	2.94±1.14
...communicating with the owner of apartment?	9 (7%)	15 (11.7%)	48 (37.5%)	28 (21.9%)	27 (21.1%)	1.27±1.15
...with the food?	18 (14.1%)	36 (28.1%)	40 (31.3%)	16 (12.5%)	18 (14.1%)	2.84±1.23

Educational and social aspects

Students had to rate on a scale from 1 (*very unsatisfied*) to 10 (*very satisfied*) their level of satisfaction in relationship with administrative staff, colleagues or teachers. The means and standard deviations are presented in tab. III.

TABLE III

The answer to the items targeting the level of satisfaction in relationship with colleagues, teachers and administrative staff

How satisfied are you with the relationship with ...	Mean and standard deviations
The relationship with the administrative staff	5.63 ± 2.27
The relationship with teachers	6.36 ± 2.11
The relationship with colleagues	6.99 ± 2.10

Students were also asked about the country where they would like to practice after graduation. A total of 43% of students would like to work as a physician in Israel, 9.4% in France, 5.5% in Germany, 4.7% in Romania, 3.9% in Greece or the United Kingdom and 3.1% in the United States. The other countries mentioned where: Netherlands, Italy, Canada, Maldives, Morocco, Taiwan and Australia.

The analysis of data identifies no significant difference considering the type of faculty (dental medicine or general medicine) regarding the level of comfort with neighbors, transportation or food or satisfaction with the relationship with the administrative staff, colleagues or teachers.

Considering the level of satisfaction, the results revealed that male students are more satisfied with their relationship with colleagues compared to female students. No other significant differences between men and women were identified considering the gender of students.

The present research is the first one developed in Romania. Medical universities are having a long experience in providing facilities to international students, but in the last decade the number of students coming from abroad have increased and the diversity of cultures, nationalities and religious is also larger. Providing services and facilities for all international students is an important and difficult goal but helping them to integrate in the new culture for their long period of studies must be taken into consideration by the university's administration. Some studies proved that the difficulty of integra-

tion and the stress related to acculturation are important factors related to depression and suicide ideation. The difficulty is greater in case of students who don't speak the language, with a strong relationship with family of origin, (especially when there are many siblings) or in case a great discomfort (9) but consistent teachers' support and strong parental attachment are helping to cope with the stress (10).

On the other hand, international students' motivation to study in Romania and their goals for their future profession are also important for their process of accommodation in the University City or their level of comfort. Some studies developed in European countries from northern or east parts of the continent proved that the goals of studying in these countries are divers, and not always related to the prestige of the university (low cost, European country or accepting students with low level of English language). For solving these problems, governments and educational policies provided special programs (11).

The present research has some strong point and limitation: This research is important because is the first one developed in the country and results must be guiding future measures focusing on integrating international students. The limitation of the study is because results cannot be generalized because the study is focusing on a certain university. Adding subjects enrolled in other medical universities from all over the country could add significant aspects.

CONCLUSIONS

International students have criteria of choosing their academic institutions. Universities and academic staff mast take into consideration their reasons used in choosing the institution and social, cultural, religious or daily life aspects must be facilitated to help them become more integrated into the community.

ACKNOWLEDGEMENTS

EVALUATION OF SERUM C-REACTIVE PROTEIN LEVELS IN SUBJECTS WITH AGGRESSIVE AND CHRONIC PERIODONTITIS IN COMPARISON WITH HEALTHY CONTROLS

The aim of a study realized by a group of indian researchers was to evaluate and to compare the serum C-reactive protein levels in subjects diagnosed with chronic periodontitis and aggressive periodontitis. Forty-five subjects were included in the study. The subjects were divided into three groups: *group I* (subjects with clinically healthy periodontium), *group II* (subjects with generalized aggressive periodontitis), and *group III* (subjects with chronic periodontitis). For the measurement of serum C-reactive protein, blood samples were collected from all subjects. Periodontal parameters (plaque index, bleeding index, gingival index, probing pocket depth, clinical attachment loss) were assessed. Serum C-reactive protein levels were assessed by means of a commercially available high sensitivity- serum C-reactive protein enzyme immunoassay kit. The results showed that serum C-reactive protein levels were increased in group III (6.0671 ± 3.15639 mg/L) and group II subjects (4.5453 ± 2.88116 mg/L) compared to the group I (1.0180 ± 0.94069 mg/L). Serum C-reactive protein levels showed a positive correlation with all clinical parameters in group I subjects. Bleeding index (r = 0.073), plaque index (r = 0.120) showed a positive correlation with serum C-reactive protein level in group II and a positive correlation was also seen for plaque index (r = 0.492), probing pocket depth (r = 0.340), clinical attachment loss (r = 0.160), and serum C-reactive protein level in group III subjects. In conclusion, the mean serum C-reactive protein levels were found to be greater in patients with chronic periodontitis compared to those with generalized aggressive periodontitis, but there was no statistically significant difference. (Bolla V, Kumari PS, Munnangi SR, Kumar DS, Durgabai Y, Koppolu P. Evaluation of Serum C-reactive Protein Levels in Subjects with Aggressive and Chronic Periodontitis in Comparison with Healthy Controls: A Clinico-biochemical Study. *Int J Appl Basic Med Res*. 2017 Apr-Jun; 7(2):121-124).

OPERATIVE STRATEGY IN ACUTE SURGICAL ABDOMEN OF NON-TRAUMATIC EXTRAGENITAL ORIGIN ASSOCIATED WITH PREGNANCY

A. Negură, Mihaela Grigore

OPERATIVE STRATEGY IN ACUTE SURGICAL ABDOMEN OF NON-TRAUMATIC EXTRAGENITAL ORIGIN ASSOCIATED WITH PREGNANCY (Abstract): The association between acute surgical abdomen of non-traumatic extragenital cause and pregnancy is very rare, making assessment difficult. Consequently, a standard protocol of surgical conduct has not been established, making it necessary to often resort to intraoperative improvisations. These, however. (usually done last and poorly thought out) may generate errors. Such risks be reduced by using the experience of properly resolved cases reported in the literature. This article presents an operative strategy recommended in cases of a combination of non-traumatic acute surgical abdomen and pregnancy according to the position and etiology of the surgical condition and the age of the pregnancy. **Keywords**: NON-TRAUMATIC, ACUTE ABDOMEN, PREGNANCY.

The association between acute surgical abdomen of non-traumatic extragenital origin and pregnancy is very rare, thus making it very difficult to determine its incidence (1, 2). Due to the low incidence of this association, no standard surgical protocol was established, and intraoperative improvisation is consequently often resorted to. Such improvisation, however, adopted quickly and poorly thought out, can contain errors. This risk can be reduced by using properly resolved cases reported in the literature. The conclusions (hat can be drawn from studying such cases can be useful to other surgeons as well, from the perspective of potential encodings which would ensure an optimum assistance that would be possible for both components of the association. According to the moment in which the condition causing the surgical acute abdomen sets, we can distinguish between two categories: Treatment for acute surgical abdomen is performed in the first trimester of pregnancy, letting the pregnancy to evolve; the treatment for acute abdomen is also useful for the evolution of the pregnancy, reducing the risk of spontaneous abortion. In the second and third trimesters of pregnancy, the surgical acute abdomen can have a supra- or subumbilical cause.

When the acute abdominal surgical disease is **supraumbilical** and the pregnancy is under 32-33 weeks, abdominal sur-

gery can be performed first, leaving the pregnancy to evolve. Such cases have already been reported in the literature; the cases of Talwar *et al* (3), generalized biliary peritonitis caused by a perforation of the gallbladder and a large sub hepatic abscess caused by a perforation of the common bile duct; the case of Essen *et al*. (4) of duodenal ulcer; the case of Sajad *et al*. (5), 34 weeks of pregnancy associated with a splenic artery aneurysm rupture and hemoperitoneum, for which hemostasis and splenectomy were performed, and the pregnancy was left to evolve, etc. (3-5). A special situation is represented by the case of a fissured or broken splenomegaly when a difficult splenectomy is foreseen, and the pregnancy is older than 32-33 weeks. In this case, surgical intervention is recommended by performing a caesarean section with Pfannenstiel incision to create a comfortable surgical field for splenectomy, maintaining the fetus under the influence of general anesthetics for the shortest time possible. Even in the case in which the pregnancy comes near term, in the presence of a normal spleen, caesarean section with Pfannenstiel incision is performed for the same reasons described above. If a supraumbilical midline incision is necessary for the acute abdominal disease, Pfannenstiel incision is performed for the caesarean section to avoid a xifopubic incision (presenting a higher risk of postoperative hernia).

In the case in which the **abdominal surgical disease is located in the subumbilical space** (i.e. acute perforated appendicitis, ileo-ileal invagination through primitive tumor, perforation of Meckel's diverticulum, intestinal obstruction through clamp and adhesions located down into the abdominal cavity, in an old inflammatory focus or genital operator, perforated Crohn's disease, perforated ulcerative colitis, intraperitoneal abscess located in the subumbilical space), diagnosis and surgical-related difficulties could occur (6-8).

The pregnancy associated uterus develops anteriorly, as compared to the acute pathological surgical subumbilical situations mentioned above. Even a pregnancy of 32-33 weeks can cover and hide a surgical acute abdominal disease, creating great difficulties in its diagnostic and therapy. Therefore, we are obliged to start with the caesarean section (with median subumbilical incision) to reduce the uterine volume and to allow the approach of the surgical acute abdominal disease, for diagnostic and therapeutic purposes: MRI without oral or intravenous (gadolinium) contrast administration is a valuable adjunct to ultrasound during pregnancy; MRI and CT performed equally well in the evaluation of acute nontraumatic abdominal pain during pregnancy. Given its lack of ionizing radiation, MRI may be preferable (9); Aytekin O. *et al* (10) has used only MRI in the triage of pregnant patients with acute abdominal and pelvic pain, given its lack of ionizing radiation.

If the caesarean section is performed in a peritonitis environment (acute perforated appendicitis with peritonitis), it should be continued by subtotal hysterectomy (because it is more expedient and less bloody than the total one) to avoid a serious or even fatal postpartum infection of the uterine sectioned remnants for which treatment with antibiotics could not guarantee survival. It is after the caesarean section (and hysterectomy) that the acute surgical abdominal disease can be operated on. If the resection of an unviable intestinal loop is necessary in an occlusion by strangulation,

without installed peritonitis, post-caesarean hysterectomy is unnecessary (treatment with broad-spectrum antibiotics being available in this case), provided that the loop resection and enteroanasiomosis be executed in aseptic surgical conditions (without peritonitis) (Negură's case with ileal invagination through tumor, with intestinal loop resection and, at the same time, termino-terminal intestinal anastomosis, with a favorable evolution) (11).

In prolonger paralytic ileus, Parswa (12) affirms: "if the K seric level maintains at more 4 mmol/L, if any prolonged paralytic ileus persists more a week and if the general condition of health starts modifies, probably there is a mechanical cause which can hide a mechanical obstruction of the bowels". Thus, Parswa considers that laparotomy is necessary (eventually after a radiologic investigation).

Mechanical occlusion of the small intestine should be distinguished from prolonged paralytic ileus by two methods:

1. method of two vertical radiographs taken at 3-hour interval (13);

2. opaque index examination (water-soluble opaque substance administered orally or barium enema (14).

Radiotherapy must not exceed 5 rad (0.05 Gy). If the gaseous distension of the small bowel with air-fluid levels on the first radiograph remains unchanged on the second radiograph, and there is no change in the topography of the persistent, fixed air-fluid images and the colon is gasless (not seen), surgery is required (14). Stoppage in the progression of opaque index at a given time and at intestinal level suggests a diagnosis of mechanical obstruction and of emergency surgery (14). Prolonged paralytic ileus is associated with fever suggests peritonitis (15,16).

If the post-gangrene intestinal peritonitis has already set, post-c section hysterectomy is required. Schraut "recommends intestinal resection, bringing the intestinal ends to the abdominal wall as temporary stomas, postponing enter anastomosis to restore intestinal continuity for another time (because an enter anastomosis performed in a peritonitis environment does not hold and will break open)" (17). The surgery is very laborious (non-minimal), posing a vital risk, yet this catastrophic situation arises due to a late diagnosis of strangulated intestinal obstruction. For this reason, in case of an occlusion hidden behind a gravid uterus, difficult to diagnose, possibly with indirect signs of strangulation (hyperleukocytosis and acidosis), the surgeons arguing that early surgery is preferable even if the laparotomy is unnecessary, but not catastrophic.

In the exceedingly rare case in which the acute abdominal surgical disease is associated with a multipara pregnancy in the third trimester, with preeclampsia or eclampsia and liver hematoma revealed by ultrasound, caesarean section is began with to interrupt the physio pathological chain of preeclampsia and to prevent hepatic rupture and a related massive hemoperitoneum (8).

Another rare case is that of multipara pregnancy in the third trimester, with or without eclampsia, with spontaneous rupture of the spleen, most commonly two-stroke.

The first stroke is the painful syndrome in the upper left quadrant, which requires (if the fetus is alive and mature) caesarean section and splenectomy to prevent the second, more dangerous, stroke, i.e. hemorrhagic syndrome with hemoperitoneum and severe hemorrhagic collapse (18).

CONCLUSIONS

Our scientific paper is an up-dated for management of association between an acute surgical abdomen disease and pregnancy. It points out the most difficult hypostases, avoid dangerous improvisations, giving the most adequate solutions with a view to obtaining best results for mother and baby.

IATROGENIC BILE DUCT INJURIES (Abstract). Bile duct injuries may occur both in hepatopancreaticobiliary surgery and in gastrointestinal surgery, but, most commonly, during cholecystectomy (80-90%). Laparoscopic approach has increased the occurrence of these significant intraoperative accidents, although it is one of the commonly seen interventions in a surgical department. The general incidence of bile duct injuries is usually 0.4-0.8%; in classical cholecystectomy, the incidence is 0.1-0.2%, and in laparoscopic surgery, it is 0.2-0.8%. **Material and methods**: We carried out a retrospective study on a batch of 23 patients who underwent surgery, from 1997 to 2015, which shows the approach of these accidents and the proper therapeutic conduct as well. **Results:** The evolution of each case depends on how quickly the diagnostic of bile duct injury is established. Two types of injuries have been identified: 52% wounds and 48% stenosis. **Keywords:** LAPAROSCOPIC CHOLECYSTECTOMY, BILE DUCTS, IATROGENIC INJURIES

Common bile duct (CBD) injuries during classical cholecystectomy, but especially during laparoscopic cholecystectomy, are a rare case, but consistently present in worldwide surgical practice CBD injuries cause major complications with locoregional and systemic effects which, without being immediately recognised and treated, may involve vital prognosis and long-term serious sequelae.

Involving the direct responsibility of the surgeon entails psychological pressure and tendency towards precipitation, which requires co-opting an experienced colleague or referring the case to a specialised centre.

Surgical treatment should restore the CBD from a morpho-functional point of view, with immediate and especially long-term good result. The more common association of iatrogenesis in laparoscopic surgery (0.2-0.8%) indicates the involvement of side effects of technology related to visual guiding in a limited field. Approximately 77-89% of CBI causes the postoperative appearance of abdominal pain, choleperitonitis, jaundice or angiocholitis (1).

MATERIAL AND METHODS

The study represents a retrospective analysis of CBI, from 1995 to 2015, caused or treated within the clinic, following classical or laparoscopic cholecystectomy. We took 23 patients for the study, of which 19 were women (83%) and 4 were men (17%), aged between 21 and 77 years (fig. 1).

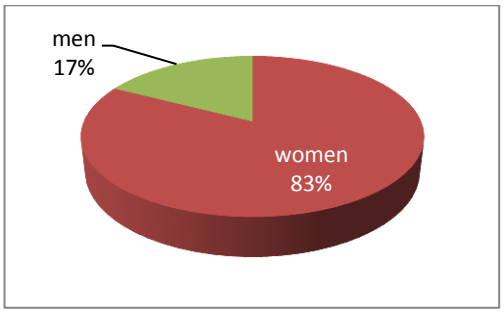

Fig. 1. Distribution depending on sex

The parameters used in the statistical analysis were represented by: initial diagnosis, intra or postoperative diagnosis of the injury, final diagnosis, surgical technique, paraclinical imaging examinations– endoscopic retrograde cholangio-pancreatography (ERCP), echography, intraoperative cholangiography, cholangio-NMR, average admission time – re-intervention, and average hospitalisation time.

The main causes of these accidents were pediculitis from the bile ducts caused by inflammation, the fact that all patients were initially diagnosed with acute cholecystitis, and biliary-vascular anatomical variations.

The identified injuries were represented by wounds of the common bile duct and stenoses of the common bile duct. The diagnosis of iatrogenic bile duct injury was established intraoperatively in 3 cases and postoperatively in 20 cases: - early (24-72 hours), in 3 cases, 2 and 3 days, respectively, after the operation; - late (>72 hours), in 17 cases, 6 cases approximately 7 days after the operation, 4 cases approximately 30 days after the operation, and the latest diagnosis of iatrogenic injury was established after 2 years.

RESULTS

Of the 23 cases, 7 cases had history of classical cholecystectomy and 16 cases had history of laparoscopic cholecystectomy, 16 cases coming from other centres. The female sex (83%) dominates the casuistry, being known the fact that biliary pathology is predominantly female. The average age of patients is 64 years.

Two types of injuries have been identified (fig. 2):

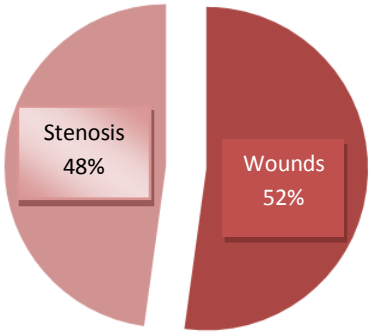

Fig. 2. Types of iatrogenic injuries

- *wounds* most commonly located at the level of the common hepatic duct, occurred as a result of a difficult dissection, due to the significant local inflammatory processes, which determined a partial or total section of the common hepatic duct; in the study, 12 wounds have been identified, of which:- 1 case with wound of the aberrant duct;- 1 case with lateral wound below the convergence + downstream stenosis;- 3 cases with lateral wound of the common hepatic duct;- 2 cases with compete section of the common hepatic duct;- 4 cases with lateral wound of the choledoch;- 1 case with section + wound of the common hepatic duct (cautery) (fig. 3).

- *stenoses* occurred because of ligature or total or partial clipping of the common hepatic duct (2, 6); the 11 identified stenoses were systematized according to the Bismuth classification:

-7 cases of Bismuth I injuries: - com-

plete choledochal ligature - 5 cases; - ligature of the common hepatic duct - 1 case;- lateral ligature of the cystic duct + common bile duct - 1 case.

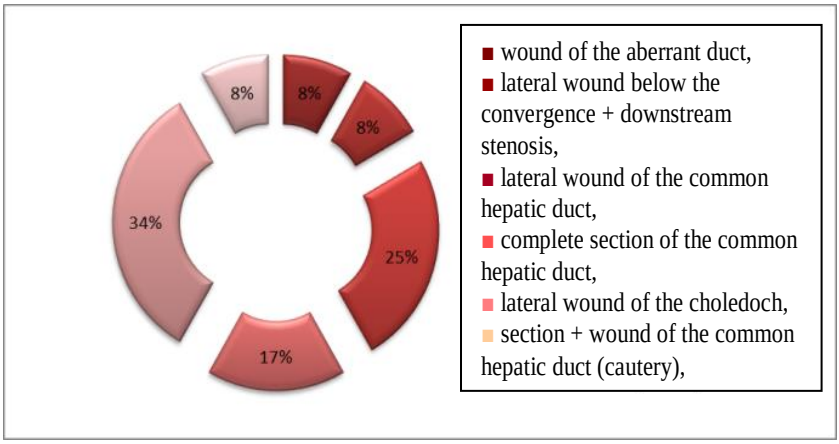

Fig. 3. Types of wounds

- 3 cases of Bismuth II injuries: - common bile duct ligatured and sectioned < 2 cm under the convergence.

- 1 case of Bismuth III injury: ligature at the level of the hilum with preserved convergence (fig. 4).

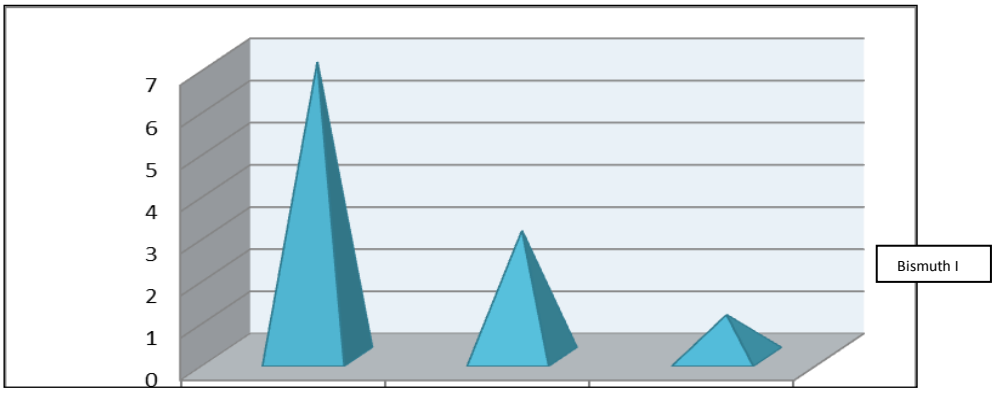

Fig. 4. Types of stenosis

According to the Strasberg classification (12), we had the following types of injuries in the studied batch: - one type C injury; - type D injuries: 8 cases;- type E1 injuries: 9 cases;- type E2 injuries: 4 cases;- type E3 injuries: 1 case (fig 5).

The main imaging explorations used for the diagnosis of the injuries were: - *abdominal ultrasound*, routine exploration, for all cases; - *intraoperative cholangiography*, which reveals leaks of contrast agent and also helps locate the injury (fig. 6, 7),

- Kehr's tube cholangiography,
- cholangio-NMR (fig. 8, 9),
- CT.

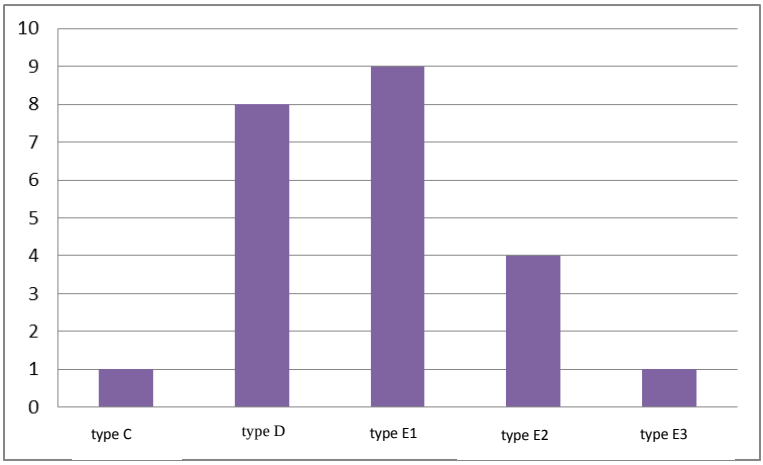

Fig. 5. Strasberg classification of iatrogenic biliary injuries

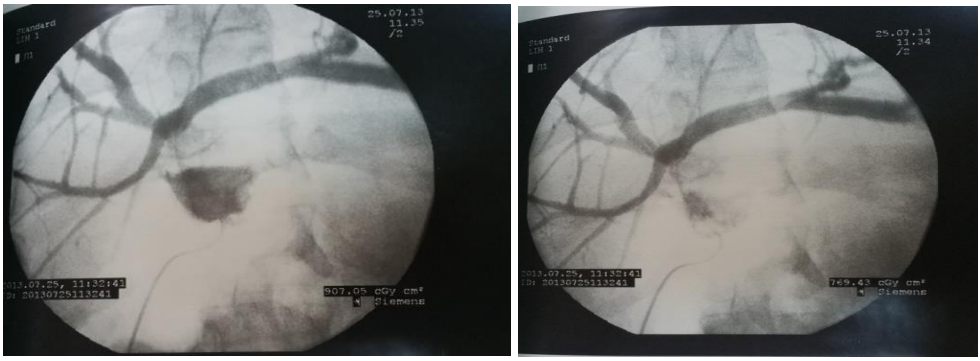

Fig. 6, 7. Intraoperative cholangiography in the patient with Bismuth III stenosis

Fig. 8. Postoperative cholangio-NMR in a patient with bile duct stenosis

Fig. 9. Cholangio-NMR in a patient with Bismuth III bile duct stenosis

The performed paraclinical explorations (blood count, biochemistry, electrolytes) reveal cholestasis syndrome in patients with iatrogenic stenosis, with high levels of total bilirubin, within the interval of 3.89-19.9 mg/dL, accompanied by phenomena of angiocholitis and sepsis, in 7 cases.

The treatment of these injuries depends on how early the injury has been recognised, and it requires experience and a technique appropriate for the type of injury. The injury was immediately identified intraoperatively in only 13% of the cases (3 patients). The approach was classical (fig. 10) and open in all cases for a better view and highlight of the injuries. The applied techniques in all 23 cases were the following:

- for stenosis:

- hepaticojejunal anastomosis with a Roux-en-Y loop - 6 cases; - hepaticojejunal anastomosis with an Ω loop - 2 cases; - T-T suture of the common hepatic duct + Kehr drainage - 1 case;- extraction of clip, suture of breach + Kehr drainage - 2 cases.

- for wounds:

- hepaticojejunal anastomosis with a Roux-en-Y loop - 3 cases; - suture of the aberrant bile duct, Kehr drainage - 1 case; - T-T suture of the common hepatic duct, transcystic drainage - 3 cases;- T-T suture of the common hepatic duct + Kehr drainage - 4 cases;- biliary drainage with two Kehr tubes in the right and left hepatic duct, one tube in the right paramedian duct - 1 case.

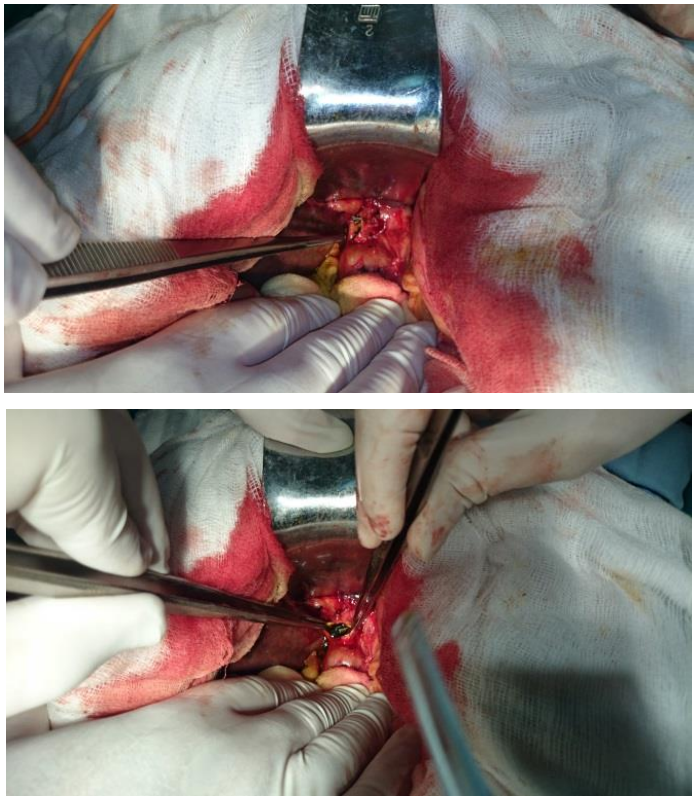

Fig. 10. Iatrogenic CBD injury - intraoperative (personal collection – C. Burcoveanu)

Morbidity was represented by the occurrence of a hepaticojejunal anastomosis fistula accompanied by choleperitoneum and septic phenomena, which cause the appearance of multiple organ failure and death, as well as the appearance of a hepatic abscess in the VIII hepatic segment, with sepsis, solved by drainage and antibiotic therapy. There were 7 cases of angiocholitis with sepsis - the association of sepsis in postoperative iatrogenic injuries, discovered late, indicate the choice of the restoration operative moment and negatively influences the results.

The mortality ratio was 4%: one patient died postoperatively due to associated personal pathologies developing septic phenomena and multiple organ failure.

DISCUSSION

Iatrogenic bile duct injuries represent a topical problem, considering the frequency of laparoscopic surgery used nowadays. They are signalled since the performance of the first cholecystectomy, in 1882, by Langenbuch.

There are multiple classifications of these injuries, depending on their location and type. The purpose of these classifications is to ease the management and choice of a proper treatment, with a surgical technique appropriate for each type of injury. Classically, the Bismuth classification is used, which is only limited to stenoses:

- I: CBD stenosis more than 2 cm from the hepatic confluence,
- II: CBD stenosis less than 2 cm from the hepatic confluence,
- III: stenosis below the confluence, but with its preservation,
- IV: stenosis at the level of the confluence, which involves both hepatic ducts, losing communication between the right and left hepatic duct,
- V: stenoses of the CBD and of a right aberrant hepatic duct (2, 3, 4).

As the Bismuth classification does not include the entire spectrum of possible injuries in the bile ducts, Strasberg *et al*. (5) have made a classification which includes that of Bismuth along with other iatrogenic injuries in the extrahepatic bile ducts:

- A: injuries of the cystic duct or the aberrant ducts from the hepatic level,
- B: stenosis of the aberrant segmental duct of the right lobe,
- C: sectioning of an aberrant segmental duct of the right lobe,
- D: lateral injuries of the CBD,
- E: stenoses or complete sections of the CBD, subdivided from E1 to E5, depending on the location of the injury according to the Bismuth classification.

Early intraoperative diagnosis is established in only 11-12% of the cases (1, 6), and, in our study, the intraoperative diagnosis ratio was around these levels, namely: 13%. Most bile duct injuries have been discovered postoperatively, late, after more than 72 hours, at variable intervals of time. For the patients in the study, the diagnosis was established with the help of imaging investigations, and they all benefited from abdominal ultrasound, while 35% of them underwent cholangio-IRM (6).

The choice of therapeutic conduct varies depending on how early the diagnosis is established, the type of injury, and the local and general physio pathological conditions (3).

In our study, most injuries were solved through reconstructive interventions (9 cases). The most used reconstructive tech-

niques to redo the biliary tree were hepaticojejunal anastomosis with a Roux-en-Y loop and hepaticojejunal anastomosis with an Ω loop, laborious techniques which require an experienced team.

Iatrogenic CBD injuries represent an undesired major complication, but possible, both in classical surgery, and especially in laparoscopic surgery.

Prevention of iatrogenesis in CBD surgery requires obsessive interest in adapting the surgical technique to the peculiarities of the case, regardless of the often-deceiving aspect of "simple gallbladder". There with, a thorough preoperative exploration and the possibility of intraoperative imaging explorations of the CBD are also required.

In our experience, along with data from the literature, the risk factors with a major impact are represented by:

- the local anatomical changes present in acute cholecystitis, but also scleral alterations from the forms of chronic cholecystitis. The choice of the operative moment in acute cholecystitis and intraoperative conversion of the technique are prevention factors of iatrogenic injuries.
- the frequency of anatomical variants at the level of the CBD, commonly accompanied by variants of hepatocystic vascularisation. Prevention of iatrogenic injuries requires preoperative and sometimes intraoperative complete exploration, and it also requires meticulous complete dissection of the anatomical structures, with no early intempestive ligatures. The approach of difficult cases is indicated in relation with the experience and level of perfection of the surgical team in classical and laparoscopic hepatobiliary surgery (7, 8, 9, 10, 11).
- If a CBD injury occurs, not complying with the specialty standard and the lack of intraoperative diagnosis technical means and of necessary materials contraindicates the resolving attempt, and the patient should be referred to a specialised centre (12,13,14).
- the perfect state of the device in laparoscopic surgery and the correct use of electrosurgery prevent possible iatrogenic injuries. The image quality in laparoscopic surgery may determine false anatomical representations, with consequences that are difficult to assess.

CONCLUSIONS

In our experience, iatrogenic bile duct injuries are serious complications that may occur both in laparoscopic and in classical surgery, associated with a high mortality, and early and long-term serious complications.

CBD injuries represent an undesired major complication, but possible. They can be prevented, but they cannot be completely avoided.

Their diagnosis is usually late, in our study, 87% of the cases being diagnosed postoperatively. Recognising the injury intraoperatively is the ideal condition of restoration intervention, with immediate and long-term favourable results. The choice of the operative moment depends on the presence or absence of sepsis and the seriousness of the inflammatory process in the CBD.

Preoperative exploration and the possibility to carry out intraoperative imaging explorations prevent the occurrence of CBD injuries.

Treatment is adapted after carrying out a complete injury report and after understanding the mechanism of how the injury occurred.

TUBERCULOSIS IN HIV-POSITIVE PREGNANT WOMEN- TWO-YEAR EXPERIENCE OF THE IAŞI REGIONAL HIV/AIDS CENTER (Abstract). **Aim:** To analyze a group of HIV-positive pregnant patients diagnosed with tuberculosis (TB) both in the intrapartum and post-partum periods and the perinatal outcomes. **Material and methods**: Over a 24 month-period (January 2015 - December 2016) we retrospectively reviewed the medical records of the patients of childbearing age actively monitored in the Iaşi Regional HIV/AIDS Center. The group included 41 pregnant women aged 17 to 39 years, three of them with confirmed tuberculosis. Data on virologic and immune parameters, level of adherence to therapy, and newborn health status were collected**. Results**: We report three cases of confirmed TB. Two of the patients were diagnosed with TB soon after delivery, and in one patient TB was diagnosed concomitantly with AIDS disease in the intrapartum period. At the time of diagnosis, all patients had suggestive symptoms, the most commonly described symptom being persistent cough lasting for a few weeks up to 4 months. Chest X-ray findings were suggestive of TB, especially in the cases with miliary tuberculosis, and in 1 patient the radiologic appearance was atypical. The diagnosis was confirmed by sputum bacteriology, positive for acid-alcohol-fast bacilli in all cases. WHO Class I anti-TB therapy along with antiretroviral therapy were initiated both during pregnancy and postpartum. In all cases the pregnancies ended in premature births at 35 weeks, the newborns being low birthweight. In immediate postpartum one patient died from sepsis of unknown etiology. **Conclusions:** Our study emphasizes the late diagnosis of TB despite the onset of symptoms several weeks earlier. We believe that the number of TB cases among HIV-positive patients of childbearing age is much higher, the implementation of a questionnaire-based screening for the early diagnosis being essential for reducing mortality. Successful treatment requires a good multidisciplinary collaboration. **Keywords:** PREGNANCY, TUBERCULOSIS, HIV, MULTIDISCIPLINARY COLLABORATION.

HIV infection is a risk factor for the progression of latent *Mycobacterium tuberculosis* infection to active TB. The risk of TB is 25-30 times higher among the HIV-positive persons compared with the HIV-negative ones. HIV-positive people are so vulnerable to primary progressive TB that the active disease may develop several

weeks after exposure to the Koch bacillus (KB). Risk factors for developing TB are: low CD4 cell count, high viral load, and non-compliance and non-adherence to antiretroviral therapy (ARV), late presentation to the doctor, anemia and decreased body mass index (1).

Tuberculosis can occur during pregnancy due to stress induced by it, especially when associated with poor nutrition, unfavorable socioeconomic background or immunodeficiency. Signs of maternal TB can range from mild cough, lasting for at least two weeks, fever and fatigue, to weight loss or hemoptysis. Pulmonary TB is the most common form of maternal TB, and of the extrapulmonary forms the most frequently reported are tuberculous meningitis and lymph node TB (2). According to literature data, TB increases the risk of prematurity and spontaneous abortion (3). Newborn infants born to both mothers suffering from TB or AIDS are more likely to be low birth weight and to have fetal distress. The exact risk of TB transmission to the newborn has not been fully elucidated. Progression from infection to disease is highest during the first year of life. Signs suggestive of active tuberculosis in children are fever, cough and poor weight gain in the context of contact with people with BK-positive sputum microbiological examination (4).

This study aimed to analyze a group of HIV-positive, pregnant or postpartum women as well as the perinatal outcomes, to determine the presence or absence of a TB diagnosis. We retrospectively reviewed the medical records of the patients of childbearing age actively monitored in the Iaşi Regional HIV/AIDS Center over a 24-month period (January 2015 - December 2016). During this period 41 pregnant women aged 17 to 39 years were admitted. In patients with confirmed TB the following data were collected and analyzed: virologic and immune parameters, level of adherence to antiretroviral as well as tuberculostatic therapy and the newborn health status. Of the study cases, only 2 were diagnosed with tuberculosis in the immediate postpartum period and 1 case in pregnancy, when a concomitant diagnosis of AIDS disease was made.

CASE REPORTS

Case 1

A 19-year-old female patient was diagnosed with stage B2 HIV infection during her first pregnancy, at 5 months' gestational age. ARV therapy with lopinavir/ritonavir and lamivudine/zidovudine was initiated. The pregnancy follow-up was not optimal, the patient skipping her follow-up visits. She delivered prematurely at 35 weeks gestational age a male baby born alive, birth weight 1930 g, Apgar score = 7. The newborn received ARV prophylaxis with zidovudine and lamivudine. In the immediate postpartum the patient presented cough, low grade fever, with patient-declared onset of symptoms 4 weeks earlier, and intrafamilial TB contact. Tuberculin skin test (TST) was negative at 72 hours, chest X-ray showed bilateral reticulomicronodular and "honeycomb" appearances, and sputum bacteriology was positive for acid-alcohol-fast bacilli (AAFB), 2+. She was diagnosed with miliary TB and received WHO Class I anti-TB therapy (isoniazid, rifampicin, pyrazinamide, ethambutol), as recommended by her pulmonologist. Shortly after the postpartum period she was transferred to the Iaşi Regional HIV/AIDS Center with a marked immunosuppressive state, CD4 count = 99 cells/mm^3 and viral load (VL) = 936.000 copies/mL (tab. I). Under these circumstances the patient developed severe sepsis with *Enterococcus faecium* isolated in

blood cultures and urine culture and *Escherichia coli* in lochia culture. HAART (highly active antiretroviral therapy) and anti-TB drugs were associated with antibiotic therapy according to the antibiogram. She developed tuberculous pleurisy and drug-induced hepatotoxicity, reason why, after pulmonology reassessment, the replacement of rifampicin by streptomycin was decided. The patient needed sustained psychological support due to recurrent depressive episodes (5). The outcome was favorable, with no relapses after nine months of anti-TB therapy, increase in CD4 count to 267 cells/ mm^3 and undetectable viral load (tab. I).

Case 2

A 27-year-old female patient belonging to the "pediatric cohort", monitored in the Iaşi Regional HIV/AIDS Center since 1999, on HAART with abacavir/lamivudine and raltegravir, stage B2 HIV infection, presented in July 2016 for virologic-immunologic assessment. As the patients stated the absence of menstrual periods, a gynecologic examination was recommended and an ongoing pregnancy, 12 weeks' gestational age, was diagnosed. In the third month of pregnancy the CD4 count = 302 cells/mm^3 and VL = 476,000 copies/mL. Her past medical history revealed one full term pregnancy, the baby being HIV-negative at the age of 18 months. She received psychological counseling to increase compliance and adherence to ARV therapy (6).

Incompletely followed-up during pregnancy, the patient delivered prematurely, at 35 weeks gestational age, a baby girl, birth weight 1750 g and Apgar score 7. The newborn baby received antiretroviral prophylaxis. In the immediate postpartum the patient presented ineffective productive cough and fever, and was transferred to our service. The patient was unable to pinpoint exactly the time of symptom onset, saying only that she had discontinued the ARV therapy for several months. Chest X-ray revealed a hyper transparent area of 10-15 cm in diameter located in the right upper lobe and homogeneous, medium intensity opacity located in the right lower lobe (fig. 1). Sputum bacteriology was positive for AAFB, 3+. The pulmonologist made the diagnosis of pulmonary TB and initiated the WHO class I anti-TB therapy.

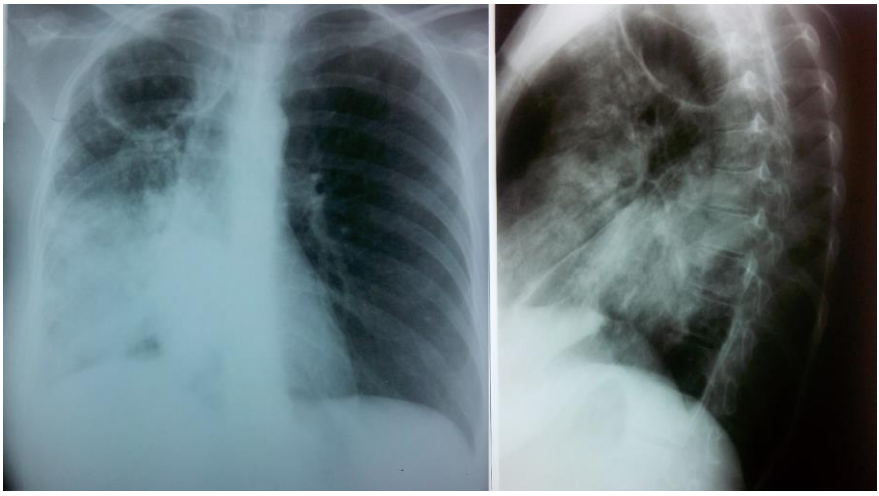

Fig. 1. Atypical radiographic appearance of pulmonary TB

CD4 count at the time of TB diagnosis was 262 cells/mm^3 and VL 150,000 copies/mL (tab. I). The outcome was unfavorable due to the occurrence of sepsis of unknown cause. Despite the complex regimens instituted, the patient died.

Case 3

A 32-year-old female patient without significant past medical history with ongoing pregnancy, 23 weeks' gestational age, presented to the Emergency Department of the Iaşi "Sf. Spiridon" County Clinical Emergency Hospital "for impaired general condition". She complained that about four months earlier she started experiencing loss of appetite, rare episodes of productive cough and difficulty swallowing, symptoms that worsened over several days before ED presentation and were accompanied by fever. The complete blood count (CBC) revealed severe leukopenia and anemia. The patient was referred for further investigations at the "Sf. Parascheva" Infectious Diseases Hospital. Serology was HIV positive, with CD4 count = 6 cells/mm^3 and VL =189,000 copies/mL being recorded (tab. I). Chest X-ray examination revealed the presence of intense micronodular opacities in both lung areas and sputum bacteriology was positive for AAFB, 2+. A diagnosis of stage C3 AIDS disease and miliary pulmonary TB was made concomitantly, and ARV therapy and WHO class I anti-TB therapy were immediately initiated.

She delivered at 35 weeks' gestation a 2,400-g viable male infant who was in distress. The newborn received ARV prophylaxis (zidovudine and lamivudine) from the first day of life. On completion of anti-TB therapy, CD4 count=316 cells/mm^3 and V=28 copies/ mL was recorded (tab. I).

TABLE I

**Virologic and immune parameters
at the time of TB diagnosis and completion of anti-TB treatment**

No.	TB diagnosis		Treatment completion	
	CD_4 count	VL	CD_4 count	VL
Case 1	99 cells/mm^3	936,000 copies/mL	267 cells/mm^3	undetectable
Case 2	262 cellsmm^3	150,000 copies/mL		deceased
Case 3	6 cells/mm^3	189,000 copies/mL	316 cells/mm^3	28 copies/mL

DISCUSSION

TB and HIV/AIDS are independent risk factors for maternal mortality; at all ages the problem is how and when they are discovered. The diagnosis of TB as well as of HIV infection has been delayed either because of the nonspecific symptoms, such as malaise, or because of seeking medical help late. WHO recommendations for the management of tuberculosis include a plan for screening using a clinical algorithm comprising four main symptoms: cough lasting at least two weeks, night sweats, fever, or weight loss. Also mentioned is the need for collaboration between medical specialties so that these symptoms to be detected and the patient referred for further investigation, regardless of the medical service where the patient was assessed (7).

It was found that pregnant women diagnosed with TB had a marked immunosuppressive state due either to non-compliance and non-adherence to ARV therapy or because of the late discovery of HIV infection. Of diagnostic relevance were both the personal history of patients - persistent

cough for several weeks up to 4 months - and household TB contact. Unless specifically asked about TB symptoms, the disease was not detected in the studied group. It was found that even the TB type depended on the CD4 count, the 2 reported cases of miliary TB having CD4 counts below 100 cells/mm^3.

The sensitivity of traditional diagnostic methods diminishes with the progression of immunosuppression. Due to the altered cellular immune response, the tuberculin skin test gave false-negative results. The diagnosis was made by sputum bacteriology positive for AAFB and radiological findings, although according to literature data the radiographic pattern is atypical when CD4 counts are below 200 cells/mm^3 (8).

In immunocompromised patients TB is difficult to diagnose as the classic diagnostic methods can give inconclusive results and the disease often remains underdiagnosed.

WHO class I anti-TB therapy along with HAART were immediately initiated, both in the immediate postpartum and during pregnancy. WHO international guidelines recommend that regardless of the CD4 count ARV therapy should be started as soon as possible, up to eight weeks, after the initiation of anti-TB therapy (7, 9).

As a side effect, drug-induced hepatotoxicity was recorded in one of the 3 reported cases, requiring replacement of rifampicin with streptomycin under the guidance of a pulmonologist. During the acute phase of tuberculosis an increase in viral load was noticed. Active tuberculosis accelerated the AIDS-induced immunological alteration, favoring the development of other opportunistic infections and death in a patient by sepsis.

TB in HIV-positive pregnant women had a negative impact on perinatal and also on infant outcomes. Deliveries were premature, at 35 weeks' gestation; newborns were low birthweight, and one of them presented fetal distress.

Infants received ARV prophylaxis from the first day of life and were also assessed for clinical and radiological signs of TB. None of them was found HIV-positive or having TB.

CONCLUSIONS

Our study emphasizes, based on this case series, the late diagnosis of TB despite the onset of symptoms several weeks earlier. We believe that the number of TB cases among HIV-positive patients of childbearing age is much higher, and the current study is merely the tip of the iceberg. Consequently, the screening for TB of HIV-positive women of childbearing age by implementing a questionnaire for the signs and symptoms of TB should be performed at the Iaşi Regional HIV/AIDS Center.

We also found that HIV/TB coinfection during pregnancy caused premature birth of low-birthweight infants, so the fetal risk should always be considered.

Treatment success depends on patient adherence and compliance to treatment, time of diagnosis, and an effective cooperation of the multidisciplinary team, including the psychologist.

NEWS

A NEW LINK BETWEEN CARDIAC DISEASE AND CEREBRAL ISCHEMIC LESIONS

Numerous studies have shown that vessel brain disease which affect inner-brain areas are responsible for cognitive dysfunction and dementia. Identification of specific markers of cerebral ischemic lesions and their risk factors could have an important role in preventing cognitive impairment. A cohort study, published online in *JAMA Neurology*, shows that biomarkers of cardiac disease are associated with cortical cerebral microinfarcts (CMI), as marker of small-vessel brain ischemic disease. The study included 243 participants to which were carried neuropsychological evaluation, determination of plasmatic concentration of two biomarkers of subclinical and clinical cardiac disease (N-terminal pro–brain natriuretic peptide and high-sensitivity cardiac troponin T) and magnetic resonance imaging for highlight of CMI. Also, for all participants, has been investigated the history of atrial fibrillation, ischemic heart diseases, or congestive heart failure. The results showed that all 70 patients (28.8%) to which were found CMI had a significantly higher prevalence of cardiac disease, such as atrial fibrillation (rate ratio [RR], 1.62), ischemic heart disease (RR, 4.31), and congestive heart failure (RR, 2.05), compared to participants without CMI. Also, participants with CMI had significantly higher levels of plasmatic biomarkers of subclinical and clinical cardiac disease (RR, 3.16 and RR, 2.17, respectively). In researcher's opinion, these results suggested that cardiac disease may contribute to the development of CMI. Thus, they have linked cardiac disease to cerebral ischemic lesion that has been previously associated with cognitive pathology, such as dementia and suggested that controlling cardiac risk factors could reduce the progression of CMI and prevent cognitive impairment (Saima Hilal, Yuek Ling Chai, Susanne van Veluw, et al. Association between subclinical cardiac biomarkers and clinically manifest cardiac diseases with cortical cerebral microinfarcts. *JAMA Neurol*. Published online February 6, 2017).

PERIOPERATIVE IMMUNE RESPONSE ALTERATION. CAN IT INFLUENCE CANCER RECURRENCE? (Abstract**)**: The relationship between host immune response and tumor cells is currently defined by the immunoediting concept, including three phases: elimination, equilibrium and escape. Cancer cells are initially eliminated by the immune system, but progressively can develop escape mechanisms. The balance between elimination and escape depends on the prevailing activity of cytotoxic Th1 or immunosuppressive Th2 lymphocytes. Surgery has the potential to eradicate the disease, but, along with other perioperative circumstances, can induce a variable degree and period of immunosuppression. By modifying the Th1/Th2 ratio, these perioperative circumstances may favor the escaping mechanisms and, consequently, promote cancer recurrence and metastasis altering long term prognosis of cancer patients. **Keywords**: CANCER, SURGERY, ANESTHESIA, PERIOPERATIVE PERIOD, CANCER RECCURENCE, IMMUNOSUPRESSION.

Cancer represents today a major source of morbidity and mortality worldwide. In the United States, the risk of developing any type of cancer during a lifetime is currently estimated at one in two for men and one in three for women. A report of American Society of Clinical Oncology states that, in 15 years from now, the prevalence of the disease will markedly increase and cancer will exceed heart diseases in terms of mortality, becoming the leading cause of death (1).

Facing this reality, researchers from around the world are struggling to find new early diagnostic strategies and to improve actual therapeutic armamentarium. Despite the introduction of new screening tools, cancer is diagnosed in the clear majority of patients when tumor cells compromise the organ function. However, the leading cause of death in cancer patients is not related to the complications of primary tumor, but rather with the occurrence of local recurrence and distal metastasis (2).

Risk factors for cancer recurrence are multiple, depending on the initial stage of disease, biological features of the tumor, initial therapy and immune function. In clinical practice the modifiable factors are the quality of the applied treatment and the abil-

ity to influence the patient immune system.

The current multimodal approach of cancer patients includes chemotherapy, radiotherapy, surgery and immunotherapy. Surgical resection is the primary treatment in solid tumors and has a curative intent in localized disease. By the same time, the surgical procedure, along with other perioperative interventions, can induce variable degrees and periods of immune suppression, favoring cancer cell spread.

Consequently, we may conclude that the perioperative period in cancer patients is related to the following dilemma: surgery represents the unique possibility to eradicate the tumor, but in the same time has the risk to promote the development of metastasis and alter the long-term outcome of cancer patients.

IMMUNE RESPONSE IN CANCER PATIENTS

The immune system plays an important role in the control of tumor growth. The initial theory of immune surveillance, formulated in 1957 by Burnet and postulating that lymphocytes are continuously recognizing and eliminating tumor cells (3), is now replaced by the immunoediting concept. Per this concept immunoediting has three phases: elimination, equilibrium and escape (4,5). In the *elimination phase*, tumoral cells are initially recognized by the innate immune system cells (macrophages) that are activated and migrate to lymph nodes to promote activation and clonal proliferation of cytotoxic T lymphocytes. Those cells migrate to the tumoral site and release enzymes responsible for tumor cell apoptosis (6). NK cells are also involved in the antitumoral response. The cytotoxic effect of cytokine activated cells is achieved by releasing perforins and granzymes responsible for tumor cell lysis (7). The presence of a T lymphocyte CD8+ and memory T lymphocytes (CD45RO+) infiltrate in the tumoral surrounding tissue is considered a favorable prognostic factor (8). In the *equilibrium phase* of the immunoediting concept, cancer cells, which have survived the elimination process, start to develop genetic mutation and progressively become resistant to the immune system. The *escape phase* is characterized by clinically apparent tumor, due to uncontrolled cancer cells proliferation. There are multiple mechanisms of tumor cells escape from the control of immune system - lack of recognition of tumor cell (lack of tumor antigens expression or MHC gene mutations), peritumoral inflammation that can inhibit the activation of CD8+, CD4+ T lymphocytes, tumor cells may induce the occurrence of Treg cells (9).

CD4+ T helper lymphocytes (Th1 and Th2 subpopulations) modulate the immune system response and can have both stimulatory and suppressive effects on cancer cells. Th1 lymphocytes secrete proinflammatory cytokines (IFN γ, IL-2, IL-12 and TNF-α) and promote an inflammatory response. Th2 lymphocytes synthesize cytokines with anti-inflammatory activity (IL-4, IL-5, IL-8, IL-10 and IL-13). The predominance of Th1 cell activation is associated with an anti-neoplastic immune response. Thus, IL-2, considered the prototype interleukin of Th1 cells, increases the cytotoxic activity of NK cells, induces the synthesis of IFN γ and activate macrophages. In contrast, Th2 cytokines promote the expression of Treg, matrix metalloproteinases, invasiveness and metastasis. In the elimination phase the Th1/Th2 balance favors Th1cells activity while the escape phase is characterized by a Th2 shift.

RISK FACTORS FOR IMMUNE SUPPRESSION DURING PERIOPERATIVE PERIOD

Cancer patients scheduled for surgery have already, in the preoperative period, multiple sources of immunosuppression. **Cancer** itself is frequently accompanied by an alteration of both humoral and cellular immune response (10). **Neoadjuvant therapies** (chemo/radiotherapy) produce destruction of cancer cells, but also of immune cells. **Malnutrition and cancer cachexia,** caused by systemic and local effects of the tumor depending on the size, location, histological type and stage, but also by treatment side-effects, is associated with a decreased cytotoxic activity of NK cells (11) and reduced levels of cytokines involved in the differentiation of Th1 lymphocytes (12).

Psychological stress and depression is frequently associated with cancer diagnosis and treatment. It triggers a neurohumoral response, characterized by an increased release of catecholamines and glucocorticoids, a reduction of NK cytotoxicity and a proinflammatory status and is correlated with cancer progression (13, 14).

The immunosuppressive effect of **surgery** is currently explained by the dual action of tissue trauma and surgical stress response. Surgery induces tissue damage and release of cellular debris, that will promote an inflammatory reaction. Proinflammatory cytokines (TNF alfa, IL-1, IL-6) activate hypothalamic-pituitary-adrenal axis and increase cortisol production with suppressive action on the immune system. But surgery also triggers a neurohumoral stress response, consisting of acute inflammation and hypothalamic-pituitary-adrenal axis and sympathetic nervous system activation. This complex response, proportional with the magnitude and invasiveness of surgical injury, aims initially to adapt the organ function to increased demands. When prolonged or exaggerated, this adaptive response can become harmful. The cumulative effects of released cortisol and catecholamines on immune function promote a Th2 cell dominance, with a consecutive depression of cellular immunity lasting for several days after surgery (15,16). Oncologic surgery often requires extensive tissue excision/resection, being associated with a high risk of intraoperative bleeding, **hypovolemia** and **hypotension**. The consecutive activation of the sympathetic nervous system and hypothalamic-pituitary-adrenal axis along with reduced tissue perfusion and tissue hypoxia will depressed the Th1 lymphocyte response (17). The **perioperative hyperglycemia** is the result of increased hepatic glycogenolysis and gluconeogenesis and peripheral insulin resistance. It impairs normal phagocytosis and leukocytes function and releases pro-inflammatory cytokines (18).

Perioperative anemia is a frequent finding in oncologic surgical patients due to preoperative bleeding, malnutrition, side-effects of neoadjuvant therapies and intraoperative blood loses. Immune suppressive effect of **allogeneic blood transfusion** is currently termed transfusion-associated immunomodulation (TRIM) and is characterized by the reduction of Th1 lymphocytes and NK cells count (19, 20).

Multiple techniques and drugs are available to provide appropriate anesthesia during surgery. Their influence on the long-term outcome seems to be explained by the modulation of the neuroendocrine response to stress and by the interaction with the immune system. **Anesthesia and analgesia** effects on immune function depend on the type of technique used (general anesthesia,

locoregional anesthesia or combined general anesthesia/locoregional analgesia) and the type of hypnotic and analgesic drugs. Concerning the choice of the anesthesia technique, two major retrospective analyses showed that using intraoperative locoregional analgesia instead of postoperative intravenous morphine analgesia markedly reduce cancer recurrence (21-22). This potential benefit of regional anesthesia/analgesia **techniques** can be explained by the attenuation of surgical stress response and the reduced intraoperative doses of opioids and inhalation drugs (23). **Intravenous anesthetic** drugs like ketamine, thiopental and midazolam result in a significant reduction of NK cells activity, as shown in animal studies (24-25). Conversely, propofol administration has no influence on NK cells and seems to favorably increase Th1/Th2 ratio in the postoperative period (24,26). Currently used **volatile anesthetic agents** like isoflurane and sevoflurane suppress NK cells activity and impair various lymphocyte functions in a dose and time dependent manner (23,27). **Opioids** induced immunosuppression was extensively studied in cancer patients. Morphine administration was associated with Th2 differentiation and increased glucocorticoid production (28-30). Conversely, the use of fentanyl and tramadol seems to increase the number and activity of NK cells, having protective antitumoral effects (31-32).

CONCLUSIONS

The complex interplay between immune system response and tumoral cells growth can influence cancer progression. Surgical interventions in oncological patients are focused on tumor eradication. The surgical stress response triggers a complex neurohumoral and immune reaction. Acting on an already altered immune status, the surgical procedure, anesthesia and other perioperative circumstances, induce a variable degree and period of immunosuppression, creating a window of opportunity for cancer recurrence and distal metastasis.

BLOOD LOSS MANAGEMENT IN PRIMARY HIP SURGERY: IS REINFUSION DRAIN A FEASIBLE OPTION IN MAINTAINING HEMOGLOBIN LEVELS?

T. S. Gheorghevici, A. Patrascu*, Carmen Grierosu, Liliana Savin, D. Mihailescu, P. Botez

BLOOD LOSS MANAGEMENT IN PRIMARY HIP SURGERY: IS REINFUSION DRAIN A FEASIBLE OPTION IN MAINTAINING HEMOGLOBIN LEVELS? (Abstract). The management of blood loss in primary hip arthroplasty is a controversial topic. **Aim:** To evaluate the efficacy of reinfusion drains in terms of hemoglobin levels and volume of red blood cell transfused postoperatively. **Material and Methods**: 295 patients who underwent primary hip arthroplasty were retrospectively assessed. After applying the exclusion criteria, 94 patients were included in the study and were divided into two groups: 45 patients received a reinfusion drain and 49 a suction drain. The following were analyzed: demographic characteristics of patients, preoperative hemoglobin level, 12-h and 24-h postoperative hemoglobin levels and their variations, number of transfused units of packed red blood cells, and postoperative complications. **Results:** Kruskal Wallis analysis revealed the homogeneity of the study groups (Chi-square=2.40, df=2, p=0.301). A statistically significant lower decline in mean Hb_{24} was found in suction drain group (p=0.001). Kruskal Wallis test revealed a significantly more frequent postoperative use of a higher number of packed red blood cell units in the suction drain group (Chi-square=28.70, df=2, p=0.001) compared to reinfusion drain group. **Conclusions:** We failed to demonstrate the superiority of reinfusion drains versus suction drains in maintaining hemoglobin levels. **Keywords**: ALLOGENEIC BLOOD, REINFUSION DRAIN, PRIMARY HIP ARTHROPLASTY

The development of modern society leads to an increase in life expectancy and along with of the incidence of degenerative and posttraumatic disorders of the proximal femur (1).

Hip surgery, especially hip replacement, is accompanied by significant blood loss requiring the replacement of the lost blood volume (2). Allogeneic blood transfusions pose high risks for the transmission of bacterial and viral infections, volume overload, renal failure, altered mental status, etc. (3, 4). To avoid these risks several methods have been developed: preoperative autologous blood donation, intra- and postoperative use of reinfusion drains, antifibrinolytic agents, controlled hypotension, spinal anesthesia, erythropoietin, etc. (5-7).

Reinfusion drains act on the principle of active suction of the fluid in the surgical

wound, its filtration or not, and intravenous reinfusion in order to minimize blood loss.

Although devoid of the above-mentioned disadvantages, the use of reinfusion drains remains controversial in terms of cost and efficacy in restoring the hemodynamic balance (8). Although their use has its enthusiasts (9-11), a number of studies have shown their ineffectiveness (8, 12).

The present study aims to study the efficacy of reinfusion drains in maintaining the hemoglobin levels and decreasing the postoperative need for packed red blood cells in patients with primary hip replacement.

MATERIAL AND METHODS

A total of 295 patients who underwent primary hip arthroplasty between February 2015 and March 2013 were retrospectively reviewed. After applying the exclusion criteria (tab. I), 94 patients were included in the study and were divided into two groups: 45 patients received a reinfusion drain (RD) and 49 a suction drain (SD). Data were collected from patients' clinical observation sheets and by using Unique Integrated Information System (UIIS).

TABLE I
Inclusion and Exclusion criteria

Inclusion criteria	Exclusion criteria
• Same surgeon	• Patients who refused blood transfusion
• Müller-Gay approach	• Patients with preoperative Hb levels <10 mg/dl
• lateral decubitus	• Patients with a history of thromboembolic events
• Spinal anesthesia	• Patients presenting coagulation disorders/ malignant conditions
• Age >18	• Patients presenting thrombocytopenia
• Preoperative Hb ≥ 10 mg/dl	• Patients presenting kidney disease/failure
	• Patients with cardiac insufficiency
	• Patients presenting liver failure
	• Patients on oral anticoagulants preoperatively, antifibrinolytic agents pre/intraoperatively and steroids
	• Patients presenting mental deterioration

The analyzed data included: demographics, preoperative Hb level, postoperative 12 h (Hb_{12}) and 24 h (Hb_{24}) Hb levels, their variations changes: (ΔHb_{12}), (ΔHb_{24}), number of transfused packed red blood cell units and postoperative complications.

The decision to transfuse postoperatively was made at hemoglobin levels <8 mg/dl or when symptoms of anemia were present.

A GEM Premier 3000 analyzer was used to analyze the blood samples. Statistical analysis was performed using SPSS 18.0 software. Student t, $\chi 2$ and Kruskal-Wallis tests were used. To determine the relationship between variables the multiple linear regression was used. P <0.005 was considered statistically significant.

RESULTS

Kruskal Wallis test revealed the homogeneity of the study groups by gender (Chi-square=2.40, df=2, p=0.301), mean age (p=0.059), although in group RD the mean values were slightly lower than in SD group (60.18 years and 65.90 years, respectively), and area of residence (p=0.234) (tab. II).

At the first postoperative assessment of

hemoglobin level, mean hemoglobin levels dropped significantly in both groups (p=0.001), with no significant differences between the groups (p=0.093). At the 2nd postoperative assessment, the mean hemoglobin levels decreased significantly in both groups compared to the levels recorded preoperatively (p=0.001), but in RD group the mean level was significantly lower than in SD group (p=0.001). However, hemoglobin variation was lower in the control group (tab. III).

TABLE II

Demographic characteristics of the study patients

	Group RD		Group SD		p F_{ANOVA} test
Gender	n	%	n	%	
Female	22	48.9	27	55.1	0.301
Male	23	51.1	22	44.9	
Age (years)					
30-39	3	6.7	2	4.1	0.059
40-49	4	8.9	3	6.1	
50-59	13	28.9	4	8.2	
60-69	15	33.3	17	34.7	
70-79	9	20.0	22	44.9	
80-89	1	2.2	1	2.0	
Area of residence					
Urban	26	57.8	20	40.8	0.234
Rural	19	42.2	29	59.2	

TABLE III

Mean hemoglobin level evolution by study group

Study group	N	Mean	Std. deviation	Std. error	Confidence interval		Min	Max	ΔHb	p F_{ANOVA} test
					- 95%CI	+95%CI				
Preoperative										
RD	45	13.87	1.47	.22	13.43	14.31	9.00	16.40		0.015
SD	49	13.09	1.71	.24	12.60	13.58	8.50	17.20		
Postoperative-12h										
RD	45	10.65*	1.31	.20	10.25	11.04	7.40	13.30	3.22	0.093
SD	49	10.26*	1.33	.19	9.88	10.64	7.60	12.70	2.83	
Postoperative-24h										
RD	43	10.54*	1.49	.23	10.08	10.99	6.90	13.20	3.33	0.001
SD	48	9.99*	1.05	.15	9.69	10.30	7.90	12.70	3.10	

Preoperatively, higher mean hemoglobin levels (13.87 mg/dl) were recorded in RD group compared with SD group (13.09 mg/dl) (p=0.015).

Kruskal Wallis test revealed that a higher number of packed red blood cell

units were significantly more commonly used postoperatively in SD group (Chi-square=28.70, df=2, p=0.001) compared to RD group (fig. 1).

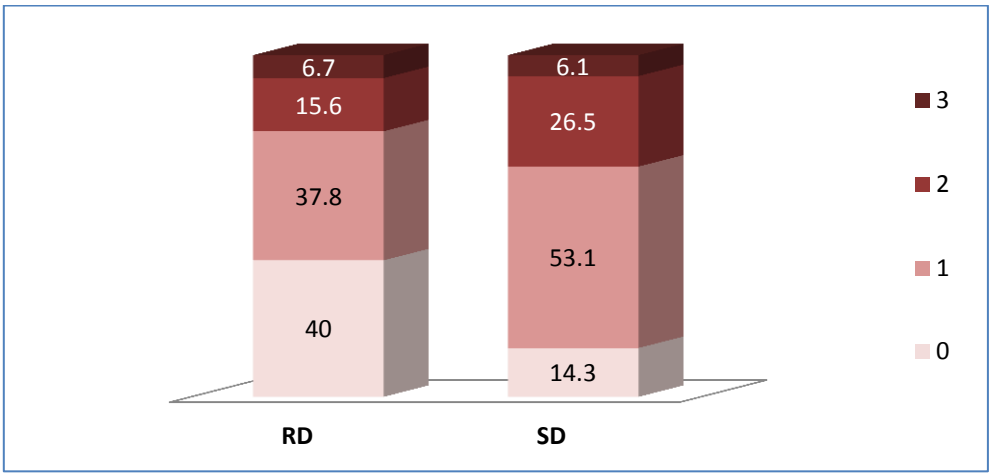

Fig. 1 Structure of groups according to the number of red blood cell units given (%)

No drain-related postoperative complications were recorded.

DISCUSSION

The number of postoperative allogeneic transfusion secondary to primary hip arthroplasty surgery is increasing (13, 14). Besides their obvious benefits, transfusions carry high risks (3) that could be reduced through the effective management of intra- and postoperative blood losses.

There are numerous studies comparing the efficacy of reinfusion drains versus the administration of antifibrinolytic substances (8, 10) but, to our knowledge, this study is the first to compare the effectiveness of two types of drains.

Our study has some limitations. Although, it is a retrospective nonrandomized study and includes a small number of patients, Kruskal Wallis test revealed homogeneity of the lots.

Our data were collected from clinical observation sheets, which involved some degree of subjective judgement. To minimize these errors a sole person collected data.

The study excluded the high-risk patients, fact that may affect the applicability of study to the general population.

The comparative analysis did not take into account patients' coagulation profile that could have influenced the postoperative bleeding and requirement for allogeneic blood transfusion.

Although the number of packed red blood cell units was higher in group SD compared to RD group (Chi-square=28.70, df=2, p=0.001), preoperative mean hemoglobin level was higher in RD group (13. 87 mg/dl *vs* 13.09 mg/dl (p=0.015).

CONCLUSIONS

Our study failed to demonstrate the superiority of reinfusion drains versus suction drains in maintaining postoperative hemoglobin levels and decrease necessary of packed red blood cells.

Because postoperative bleeding is

closely connected with prognosis, it is necessary a larger prospective double blind study to confirm our results.

OUTCOMES OF SURGERY IN PROLIFERATIVE VITREORETINOPATHY (Abstract) **Aim:** To present the anatomical and functional outcomes of surgery in cases of rhegmatogenous retinal detachment complicated (at presentation) by proliferative vitreoretinopathy (PVR).**Material and methods:** Retrospective study of the cases operated upon by a single surgeon between October 2012 and September 2014.**Results:** A total of 49 eyes of 49 patients had PVR at presentation (12 cases with PVR stage B, 21 with stage C and 16 with stage D). 82% had a VA $\leq$ 0.05 at presentation. Peripheral retinectomy was the primary surgery in 57% of cases. Reinterventions was required in 16.3% of the cases (silicon oil extraction was not considered reintervention). Although at the first postoperative examination 32% of eyes had an IOP > 21 mmHg without medication, only 8% retained a high IOP at the last visit. At the last visit 73.4% of eyes presented attached retina (an additional 6% had an attached macula under silicone oil, but sub retinal fluid in the inferior quadrants). A final VA $\geq$ 0.05 was recorded in 67.3% of eyes (of which half had VA $\geq$ 0.1) **Conclusions**: In cases presenting with retinal detachment complicated by PVR the possibility of reinterventions and the risk of intraocular hypertension should be considered. Unfortunately, even some cases with favorable anatomical outcome will not present ambulatory vision. **Keywords:** RHEGMATOGENOUS RETINAL DETACHMENT, PROLIFERATIVE VITREORETINOPATHY.

The most common cause of retinal detachment is rhegmatogenous (peripheral retinal breaks). Proliferative vitreoretinopathy (PVR) is the most important complication in retinal detachment surgery (and the main cause of surgical failure). A major issue for the retina surgeon was the late presentation of patients, often weeks or months after the detachment has occurred (although the disease has an acute onset and is associated with a significant decrease in visual acuity). Consequently, a large proportion of our cases had PVR at presentation, and the aim of this paper was to analyze the postoperative course, anatomical and functional outcomes of the PVR patients operated on in our clinic.

MATERIAL AND METHODS

We have conducted a retrospective study of the cases operated on by a single surgeon between October 2012 and September 2014. Only the cases diagnosed at presentation with rhegmatogenous retinal detachment complicated by PVR were included in the study. The classification of

PVR proposed by the Retina Society Terminology Committee was used (1). All patients underwent *pars plana* vitrectomy using the 23G sutureless system (Constellation, Alcon, USA). During surgery the following were performed: peeling of preretinal membranes in the posterior pole and in the periphery (if necessary cutting or peeling of subretinal membranes), peripheral retinectomies in anterior PVR, retinal reattachment, laser retinopexy and endotamponade with silicone oil or non-expansile mixture of C2F6 and air.

The collected data included: diagnosis, type of surgery, type of endotamponade, visual acuity (VA), intraocular pressure (IOP), use of antiglaucoma medication, crystalline lens status (at baseline and at postoperative visits). The statistical analysis was performed using MedCalc (©MedCalc Software bvba), comparing preoperative and postoperative values with paired t-test, and the threshold for statistical significance was considered $p < 0.05$.

The study conformed to the principles of the Declaration of Helsinki.

RESULTS

During the study period 315 patients underwent surgery for retinal detachment. The analysis of their medical records showed that 49 eyes of 49 patients had PVR at presentation and were subsequently included in the study. Of these, 12 eyes had stage B PVR, 21 stage C and 16 stage D. The duration of symptoms at presentation (the duration of retinal detachment) was 3.9 ± 4.3 months (range 0.5-24 months). The mean age at presentation was 63.08 ± 13.72 years (range 31-64 years). The mean visual acuity was 0.02 ± 0.04 (range 0.0001-0.2), and 82% of patients had a VA < 0.05. Mean IOP at presentation was 12.4 ± 3.6 mmHg, and 3 eyes had preoperative hypotonia (IOP < 6 mmHg). The status of the crystalline lens: 4 eyes had a transparent lens (8.1%), 26 h ad various degrees of cataract (53%), 16 eyes (32.6%) were pseudophakic and 3(6.1%) aphakic.

Relaxing peripheral retinectomy was performed in 28 eyes: 180º retinectomy in 10 eyes (20.4%), 270 º retinectomy in 2 eyes (4%) and circumferential peripheral retinectomy in 16 eyes (32.6% - all cases with stage D PVR).

The postoperative visual acuity increased to an average of 0.1 ± 0.11 (range 0.001-0.4). The difference between preoperative and postoperative VA was statistically significant (p=0.0001, paired t-test). The postoperative IOP was 15.6 ± 6.3 mmHg (range 4-32 mmHg). Not all cases of postoperative intraocular hypertension needed anti-glaucoma treatment, which was usually considered when the IOP exceeded 26 mmHg.

The first postoperative visit was scheduled at 3 weeks. The visual acuity continued to increase up to 0.13 ± 0.1 (range 0.001 – 0.4). The intraocular pressure at the first visit was 20 ± 10.3 (range 8-52 mmHg) – 14 eyes had an IOP above 21 mmHg. If the retina was found to be attached, the patient was instructed to seek monthly visits with the attending ophthalmologist, including IOP measurements (local patients returned to our clinic for monthly controls).

The second visit was at an average of 11 weeks postoperatively. Mean IOP was 17.4 ± 8.5 mmHg. An IOP > 21 mmHg was recorded in 7 eyes although 6 of them were under anti-glaucoma therapy. If the retina was considered stable under the silicone oil tamponade, usually at 3 months after the first surgery, the silicone oil was removed. In 8 eyes (16.3%) with an unsatisfactory postoperative anatomical outcome (the retina being totally or partially detached) a

reintervention was recommended (peeling of retinal membranes, supplemental retinectomies, replacing the endotamponade with high viscosity silicone oil – 5000cS).

The mean follow-up was 23 weeks. At the end of this period, 36 eyes (73.4%) had a completely attached retina. To these we may add 3 eyes (6%) that had an attached macula, but persistent subretinal fluid in the inferior quadrants. The mean final VA was 0.08 ± 0.07 (range 0.001-0.3). (fig. 1) The statistically significant difference between preoperative and postoperative VA was maintained. In the end, 67.3% of the eyes had a VA greater than 0.05, of which half greater than 0.1.

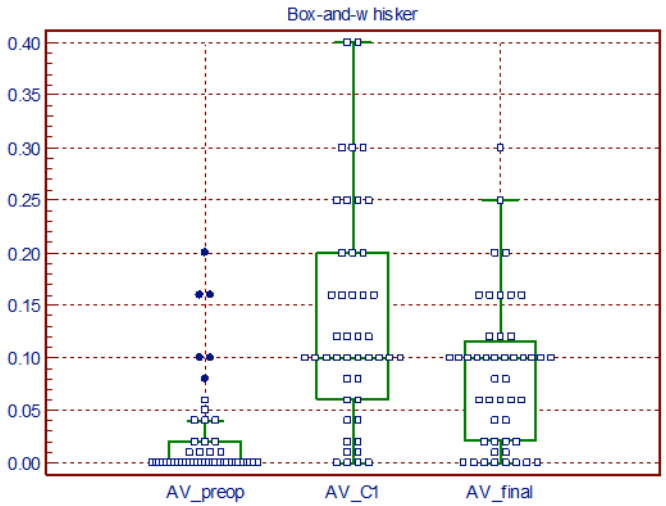

Fig. 1 The evolution of visual acuity: preoperative, at the first control visit and at the final visit

Mean final IOP was 15.6 ± 7.3 mmHg (range 2-40 mmHg). Four eyes recorded IOPs > 21 mmHg, despite the use of anti-glaucoma drops.

At the end of the follow-up period we had information on lens status in 39 cases: 10 had cataract, 16 were pseudophakic, 9 aphakic and 4 had preserved a transparent crystalline lens.

DISCUSSION

An important paper published by the European Vitreoretinal Society analyzed the surgical interventions for 7678 retinal detachments. The presence of choroidal detachment, significant hypotonia, preoperative stage C1 PVR (more advanced PVR cases were excluded), 4 detached quadrants and giant retinal breaks were identified as independent predictive factors of primary surgery failure (2). Patients with stage C1 PVR had a level 1 failure rate of 3.3%, that increased to 9.2% when a large or giant retinal break was identified (level 1 failure was defined as failed reattachment deemed inoperable by the end of the follow-up). Level 2 failure (eyes that have maintained silicone oil endotamponade by the end of the study) was present in 11.8% of the eyes with stage C1 PVR. (3)

In another multicenter trial on 555 cases that underwent *pars plana* vitrectomy and intraoperative perfluoro-n-octane tamponade

for retinal detachment complicated by PVR, the retina was attached in 78% of the eyes at the end of follow-up. The use of silicone oil or C3F8 (perfluoropropane) tamponade was considered to reduce the risk of recurrent retinal detachment (4)

Since 37 of the 49 eyes in our study had PVR stage C or higher and 79.4% had a completely attached retina at the end of follow-up, our results are comparable with those found in the literature.

A recent meta-analysis of randomized trials concluded that in retinal detachment complicated by PVR, the use of C3F8 or silicone oil tamponade is reasonable (5). In our series, most patients received a silicone oil tamponade.

In a recently published paper, 30.5% of the eyes with silicone oil tamponade had elevated IOP at 2 weeks, and 12% maintained a high IOP on medium term. (6) This tendency was also observed in our patients, at the end of the follow-up 8.16% maintaining an IOP greater than 21 mmHg with anti-glaucoma drops.

CONCLUSIONS

The outcomes of surgery for the most important complication of retinal detachment in our study are similar to those reported in the literature. In the cases complicated by PVR at presentation the patient should be informed of the high rate of reinterventions for recurrent retinal detachment and the risk of postoperative intraocular hypertension. Unfortunately, some cases with a favorable anatomical outcome do not achieve a satisfactory visual function.

THE PATIENT-DOCTOR-PSYCHOLOGIST TRIANGLE IN A CASE OF SEVERE IMUNOSUPRESSION IN THE HIV INFECTION (Abstract). In the last two years the Romanian adult population infected with the human immunodeficiency virus (HIV) has increased due to sexual transmission, both heterosexual and homosexual. The case presented is that of a 33 year-old man, admitted to the Infectious Diseases Hospital in Iasi with acute respiratory failure and a confirmation of Kaposi's sarcoma. Tests later proved positive for HIV, the patient being included in the stage AIDS C3 (acute immunodeficiency syndrome).The respiratory failure was suspected to be caused by *Pneumocystis carinii* and cotrimoxazol therapy, oxygen therapy and anti-retroviral therapy were established. He was also referred to the oncology hospital for treatment of Kaposi's sarcoma. The patient's adherence to therapy was influenced by a strong doctor-patient relationship, as well as by psychological counseling and support. Creating a functional doctor-patient-psychologist team is key throughout the HIV-positive patient's existence, for supporting long term adherence to therapy and acceptance of the diagnosis. This case highlights the need for a strong psycho-social compartment in every medical center that deals with HIV-infected individuals. **Keywords**: HIV/AIDS, ANTIRETROVIRAL THERAPY, PSYCHOLOGICAL COUNSELING, DOCTOR-PATIENT RELATIONSHIP.

The HIV/AIDS pandemic has reached 36.9 million people globally living with HIV. At the end of 2014, two million people became newly infected with HIV, and 1.2 million people died from AIDS-related illnesses (1).

In Romania, the main characteristic of the HIV/AIDS population is the development of the "pediatric cohort", represented by HIV positive youth infected as children in the 1990's (2). This group is currently being equaled in numbers by newly infected cases. The most common means of transmission for these new cases are unprotected sexual intercourse, both heterosexual and homosexual, as well as use of injected drugs (3).

In the North-Eastern part of Romania, in October 2015 there were over 1400 people living with HIV/AIDS, this year being the first in which the number of newly diagnosed adults has equaled that of the

"pediatric cohort". The infection is transmitted mostly by heterosexual and homosexual unprotected intercourse and less through intravenous administration.

CASE PRESENTATION

We present the case of a male patient, born in 1980. This patient was transferred to the HIV/AIDS Regional Center by a local clinic, in August 2013. The reasons for hospitalization were: weight loss, fatigue, impaired general condition, acute respiratory failure, perioronasal cyanosis and of the extremities, with preserved consciousness. At admission, the weight was 53 kg, height 163 cm and 76% partial oxygen pressure.

From the patient's statements, his weight decreased progressively, 12 kg in 4 months. For the last 10 months, he developed lenticular brown spots on the skin, disseminated on the trunk, abdomen, and the upper right eyelid. There were no significant pathological aspects in the personal and family history. The biological samples from the County Hospital were near normal, except for hemoglobin 10.8 g/l, the appearance of "mat glass" of the chest X-ray, and also the positive result for HIV 1 and 2 ELISA test. Upon more in depth interrogations about the patient's personal history, he identifies the means of getting infected with HIV as unprotected homosexual intercourse.

Viro-imunologic tests show a profound immunosuppression, with CD4 2 cells/mmc (fig. 1) and a viral load (VL) of 518000 copies/ml (fig. 2). The dermatologic examination established the clinical diagnosis of Kaposi sarcoma, confirmed by skin biopsy. Serology for cytomegalovirus (CMV), toxoplasma, hepatitis B and C were negative, with also a negative VDRL. The major suspicion in the context of pulmonary failure was pulmonary pneumocystis, and therapy was initiated with cotrimoxazole 8 tablets / day, intermittent oxygen, decreasing cortisol dose. Antiretroviral therapy immediately instituted was achieved with co-formulations of lopinavir + ritonavir and lamivudine + zidovudine and enfuvirtide (T20 Fuzeon). The pulmonary phenomena remitted extremely slowly, with the possibility of transfer within 30 days in the oncology ward of the county hospital, where specific therapy for Kaposi's sarcoma was initiated.

The patient, being a university graduate, showed a high level of intelligence and seemed to understand his situation. The infectious diseases doctor managed to create a relationship with this patient based on mutual trust, which encouraged him to own his diagnosis, expressing the desire to overcome this obstacle.

Throughout the hospitalization the patient benefited from psychological counseling and support after diagnosis disclosure. This added the psychologist to his support network, alongside the infectious diseases doctor. Counseling sessions consisted in semi-structured interviews about the patient's personal and medical history, as well as free discussions regarding topics of interest for him – family, work-place, intimate relationships, social stigma. The main objective of was to explore fears and emotions linked to the HIV diagnosis, assisting the patient in dealing with them in a healthy and productive manner. The result of counseling and support were seen in a good compliance and adherence to antiretroviral (ARV) therapy, while resuming his daily routines and activities.

Three months after the first episode, the respiratory failure was resolved. The CD4

cell count increased to 92 cells/mmc (fig. 1), and the viral load decreased over 100 times, VL 5530 copies/ml (fig. 2). Cotrimoxazole prophylaxis was maintained, reducing the dose to 2 tablets every 2 days, with continued ARV treatment and specific cancer therapy.

In May 2014 the viral load remained high viral and CD4 increased slightly.

However, in October 2014 VL grew to 12.800 copies/ml (fig. 2) and CD4 cell count dropped to 65 cells/mmc (fig. 1). The patient admitted that, after a period of good general condition, and after discontinuing therapy with enfuvirtide, he began to neglect antiretroviral therapy up to 3-4 days a week.

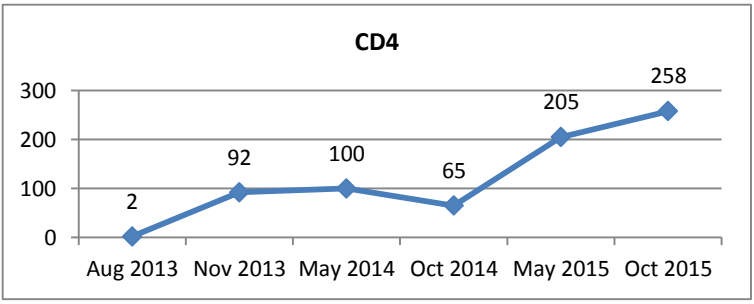

Fig. 1. CD4 cell count

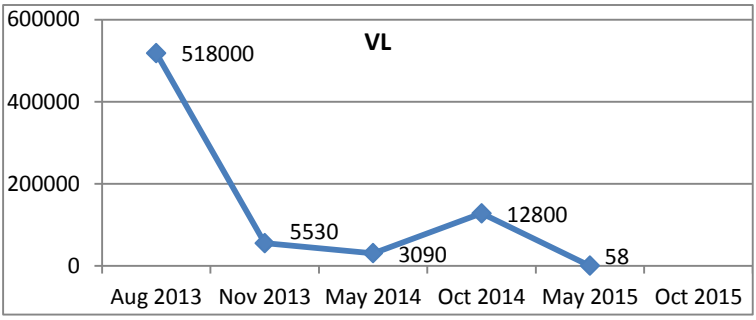

Fig. 2. Viral load

Daily psychological sessions were resumed, as well as repeated discussions with the infectious diseases doctor. These aimed to explore the patient's reasons for non-adherence and help him identify ways to prevent this in the future. The main objective was to increase long term adherence and compliance to ARV therapy. On discharge the patient seemed willing to maintain his adherence to therapy.

In the month of May 2015, biological evaluations showed a CD4 count of 205 cells/mmc (fig. 1), and VL a little over the detection limit - 58 copies/ml (fig. 1), with a weight gain of 8 kg. The oncology therapy with interferon solved the Kaposi lesion on the upper left eyelid and faded the other elements on the skin. The prophylaxis for pneumocystis with Cotrimoxazole was suppressed because CD4 cell count rose above 200 cells / mmc.

On the 29th of October 2015 the patient

had 78 kg, with a plus of 25 kg compared to the time of his first presentation. The Kaposi sarcoma faded, his viral load was undetectable, and CD4 was 258 copies / mmc.

DISCUSSIONS

The case presented is that of an intellectual patient with very severe immunosuppression caused by HIV infection. He had the chance to overcome a complex, extremely aggressive and life-threatening pathology, with acute respiratory failure and disseminated Kaposi sarcoma.

Initially, his results were good, due to the possibility of a smooth communication and understanding of diagnosis and both therapy benefits and risks of non-adherence.

The patient received psychological support throughout the hospitalization. Counseling sessions focused on internalizing information regarding the diagnosis, and especially on building a positive self-image, strengthening self-respect and shaping positive future projections.

The therapy was based on the very probable etiology of respiratory failure – that of pneumocystosis, as well as on the Kaposi's sarcoma. This specific therapy, alongside antiretroviral therapy, encouraged an increase of the immune competence over time, successfully managing the case (4,5).

However, therapeutic indications were apparently not enough. The patient's high coefficient of intelligence and education were a baseline in establishing a productive patient-doctor relationship, but were not sufficient in providing long-term support for adherence. Daily clinical practice in the HIV/AIDS Regional Center in Iasi proved that, in a chronic disease such as HIV/AIDS, with lifelong daily therapy, psychological sessions are essential in offering support and helping patients find resources to cope (6,7,8).

CONCLUSIONS

Given the complexity of hospitalized cases, the management of an HIV-positive patient should be a team effort. In our study, we highlighted the fact that trust in the infectious diseases doctor, as well as confidence in one's strength to overcome the burden of the diagnosis are as important as ARV therapy or treating opportunistic infections.

The psychologist's intake is essential throughout the life of HIV infected patients; repeated counseling sessions are important for optimal adherence and compliance to therapy, in order to achieve viro-imunologic success and social integration. The need to adapt daily life and routines to new diagnosis requires its total acceptance; the support that people diagnosed with HIV receive facilitates this process of adaptation.

Therefore the development of a psychosocial department with trained professionals in the pathology of HIV/AIDS is more than necessary in managing the success of any case of HIV infection. The triangle formed by the doctor, the patient and the psychologist, working as a team toward a common goal, is the key to a successful management of the disease and should be a model included in every center that treats HIV pathology.

NEWS

ASPIRIN USE AND COLORECTAL CANCER

Colorectal cancer (CRC) is the second most frequent type of cancer in Europe, with higher incidence for men after 50 years of age. Aspirin has anticancer effects. The aspirin use reduced the colorectal adenomas risk and the distant metastasis for patients with CRC. A recent meta-analysis summarized the results of eleven studies and showed that aspirin therapy after CRC diagnosis improved survival particular among patients with positive prostaglandin endoperoxide synthase 2 (PTGS2) expression and mutated PIK3CA tumors. PTGS2 is an enzyme involved in prostaglandin synthesis which promote inflammation and cell proliferation. Phosphatidylinositol 3-kinase (PI3K) has an important role in carcinogenesis. Also, the meta-analysis highlighted no association between aspirin use before diagnosis and CRC mortality. Future research is needed in order to establish the optimal doses and duration of aspirin adjuvant therapy in CRC (Peiwei Li; Han Wu; Honghe Zhang; Yu Shi; Jinming Xu; Yao Ye; Dajing Xia; Jun Yang; Jianting Cai; Yihua Wu. Aspirin use after diagnosis but not prediagnosis improves established colorectal cancer survival. *Gut* 2015;64(9):1419-1425).

PECULIARITIES OF PHARMACOTHERAPY IN ARTERIAL HYPERTENSION AND COMORBID PATHOLOGY (Abstract): In patients with arterial hypertension (AH) pharmacotherapy often remains ineffective because of comorbid pathology. Research of haemodynamic and metabolic processes in such patients allows prescribe effective antihypertensive medicines, improve life quality and prognosis. **Material and methods:** 60 patients with AH, coronary artery disease and obesity were divided into three groups: 1st group was treated with lisinopril + atorvastatin + aspirin (regimen I); 2nd group was treated with lisinopril + atorvastatin + bisoprolol + aspirin (regimen II); 3rd group was treated with lisinopril + bisoprolol + indapamide + atorvastatin + aspirin (regimen III). Laser correlation spectrometry (LCS) was used to evaluate the homeostatic alterations. **Results:** All regimens were equally effective in normalization of systolic blood pressure and did not influence the ejection fraction. Only in the 3rd group was determined significant increase of glomerular filtration rate (92.73±2.12 vs 79.62±13.62 ml/min/1.73m^2). The LCS test showed that these patients had high level of light scattering particles IV, which may be caused by activation of anabolic processes. In other groups, spectral alterations were not so expressive. **Conclusions:** Prescription of antihypertensive therapy cause homeostatic and metabolic alterations, which may influence the efficacy of treatment. **Keywords:** PHARMACOTHERAPY, COMORBID PATHOLOGY, LASER CORRELATION SPECTROMETRY.

A considerable growth of cardiovascular diseases, especially among the elder patients, is observed all over the world and in Ukraine. Primary hypertension (PH) and coronary artery disease (CAD) are the main causes of cardiovascular morbidity (41.8% / 38.3, accordingly) [1]. PH combined with CAD make worse patient's prognosis and lead to adverse outcomes [2]. High level of systolic blood pressure is one of the main risk factors of CAD and its complications [3]. Thus, addition of CAD to PH increases cardiovascular risk to high level [4]. It was proved by PROGRESS investigation, which confirmed that every 4th death from CAD is caused by increased blood pressure [3]. In elderly patients, PH is complicated with CAD in 67.7% cases [1].

In patients with CAD combined with PH obesity is one of the most common comorbidities [5]. Our previous investiga-

tions determined negative impact of the obesity in heart failure, atrial fibrillation and decompensation of the patient state [6]. Patients with obesity and PH have high cardiac preload caused by the growth of circulating blood volume and high postload caused by high arterial stiffness [7].

In the elderly patients, choice of effective pharmacotherapy (PT) is complicated with numerous comorbidities, pharmacokinetic and pharmacodynamic peculiarities [8, 9, 10]. Nowadays there are not enough methods, which allow to determine the influence of PT on metabolic processes [8, 11]. This leads to low efficacy of antihypertensive treatment [3]. So it is important to provide complex sanogenetic monitoring in all patients with PH. Laser correlation spectrometry (LCS) is one of the most common methods, which allows quickly determine and analyze the metabolic disorders [12, 13, 14].

MATERIAL AND METHODS

In Odessa University Clinic (Ukraine) 60 patients with PH, CAD and obesity were treated according to clinical recommendations [4, 15, 17, 18]. All patients were divided into three groups: the 1st (n=20) was given lisinopril + atorvastatin + aspirin (regimen I), the 2nd (n=20) was given lisinopril + atorvastatin + bisoprolol + aspirin (regimen II); the 3rd (n=20) was given lisinopril + bisoprolol + indapamide + atorvastatin + aspirin (regimen III). Exclusion criteria: myocardial infarction and stroke in anamnesis. Body mass index (BMI) and glomerulal filtration rate (GFR) were calculated in all patients.

The special research method for estimation of plasma metabolic features was LCS [13]. It helps to measure spectral characteristics of the induced monochromatic coherent radiation in biological liquids. That makes possible to register particles with hydrodynamic radius 1 - 10000 nanometers. Results are presented as a histogram.

According to our previous studies [13], to the I zone (0-10 nanometers) are included low-molecular monomeric albumins and glycolipid free complexes; to the II zone (11-30 nanometers) are included globulin proteins and low-molecular lipoprotein complexes; to the III zone (31-70 nanometers) are included high-molecular lipoprotein complexes, RNP-, DNP molecules, the low-molecular immune complexes; to the IV zone (71-150 nanometers) are included mainly constitutive immune complexes of the average size. Huge particles ($\geq$ 150 nanometers, the V zone) are present in patients with allergization and an autoimmune sensibilization. The particle distribution and their molecular interaction characterizes different pathological states. The presence of xenobiotics (e.g. medicines) causes specific changes of the initial distribution and may characterize the treatment efficacy. Metabolic features were determined in blood plasma before and on the 10th day of PT. The investigation was carried out according to the method after Bazhora J.I. and Noskin L.A. [14].

The statistical analyze was provided with Statistica 7.0. To measure differences between values before and after the treatment we used t-test; p-value of < 0.05 was considered to be statistically significant. Values are presented as Mean ± Standard deviation (SD).

RESULTS

Mean age (MA) of the investigated patients was 67.2±5.1 years. Among them were 28 males (MA 66.2±8.9 years) and 32 females (MA 68.3±7.4 years). All of them had obesity with BMI corresponding to the

first stage (BMI: 30-35 kg / m2). Diabetes mellitus was diagnosed in 26.31% patients in the 1st group, in 15% in the 2nd group and in 25% in the 3rd group.

Before and after the prescription of antihypertensive therapy we determined changes of heart rate (HR), systolic and diastolic blood pressure (SBP, DBP), ejection fraction (EF), total cholesterol and levels (tab. I).

After the treatment in the 1st group was determined the decrease of SBP (by 35.0 mm Hg), DBP (by 12.4 mm Hg) and HR (by 14/min). EF, GFR and glucose levels remained without any changes. Total cholesterol decreased by 1.68 mcmol/L.

In the 2nd group SBP decreased by 20.91 mm Hg. DBP, HR and EF remained the same. Cholesterol reached the normal values (4.78 mmol/L) but glucose level increased by 1.14 mmol/L ($p>0.05$).

In the 3rd group SBP decreased by 29.8 mm Hg, DBP by 14 mm Hg, HR by 9.73/min. Cholesterol level reached the target borders (4.68 mmol/l). EF and glucose level remained the same. GFR rate increased to 92.73 ml/min/1.73m^2.

LCS data showed that only regimen III caused a significant growth of light scattering particles (LSP) IV (on 11.1%), which characterize anabolic reactions. Before the prescription of regimens I and II prevalence of LSP II, III and IV was observed. It is typical for catabolic, toxic and allergy-directed reactions.

These alterations remained without any significant changes after the treatment (tab. II).

Concerning spectral alterations, we determined that hydrolytic alterations remained the same after the prescription of regimen I. Normological type even decreased by 15.0% and anabolic type increased the same value due to autoimmune reactions. Regimen II caused the decrease of hydrolytic reactions by 25.0% and growth of anabolic reactions by 15.0%. Regimen III was characterised by increase of hydrolytic and anabolic type reactions (10.0% / 25.0%, accordingly) (tab. III).

TABLE I

Clinical data of all the investigated groups before and after PT

Clinical data	Regimen I		Regimen II		Regimen III	
	Before the treatment	During the treatment	Before the treatment	During the treatment	Before the treatment	During the treatment
SBP, mm Hg	163.2±16.1	128.0±8.6*	151.3±6.2	130.4±6.0*	160.7±11.5	130.9±9.1 *

Mixed	20.0	20.0	20.0	10.0*	45.0	15.0*

*, p< 0.05 vs before treatment.

DISCUSSION.

As we observed from abovementioned data, all the three regimens equally caused stabilization of SBP, which is the main target of antihypertensive PT [19]. DBP was significantly lowered with the Ist and IIIrd regimens, but in the IInd regimen it remained without changes. Significant lowering of HR was achieved after the prescription of lisinopril. We did not determine any influence of used PT on EF rate.

In all three groups, total cholesterol level was brought to the normal values. Regimen II increased glucosa level, but not statistically significant. GFR rate didn't changed after regimens I and II, but regimen III caused growth of GFR. Thus, as we see, such a step-by-step prescription of each new drug is very convenient for observing of it's influence and helps us to optimise the treatment.

LCS data showed that regimens I and II didn't change the subfractional structure and only regimen III caused the growth of anabolic reactions. To estimate PT influence on metabolic processes we have to take into account not only subfractional structure but also directions of spectral alterations.

We also have to take into account initial alterations and compare them with alterations after the PT. Otherwise, the received data could be incorrectly interpreted.

So, regimen I caused lowering of normological type and in spite of anabolic reactions growth, hydrolytic type remained the same as before the treatment. Thus, regimen I is not effective in correction of hydrolytic reactions. Addition of bisoprolol (regimen II) caused decrease of hydrolytic reactions and simultaneous increase of

anabolic ones. So, regimen II change hydrolytic as anabolic processes. Regimen III (which included indopamide) caused increase of hydrolytic and anabolic reactions. So, as we see, we have to compare both LCS data: LSP redistribution and spectral alterations in order to estimate PT influence on metabolic processes. In our investigation spectral alterations appeared to be more informative because of proved statistical significance.

CONCLUSIONS.

All the prescribed regimens are optimal for SPB stabilization but they do not influence EF. In elderly patients with PH and comorbid pathologies PT should be individualized. LCS is very sensitive method, which allows determine homeostatic alterations and metabolic transformations in the process of treatment. Addition of LCS to basic clinical, laboratory, and instrumental data helps to choose an appropriate PT.

NEWS

EVALUATION OF CLINICAL OUTCOMES IN PATIENTS UNDERGOING DUAL VESSEL PERCUTANEOUS CORONARY INTERVENTION USING SIROLIMUS-ELUTING CORONARY STENT SYSTEM IN INDIA

The safety and efficacy of percutaneous transluminal coronary angioplasty (PTCA) has been demonstrated in selected patients with symptomatic coronary artery disease. Application of PTCA in patients with multiple vessels or in more extensive coronary artery disease has been limited, and the safety and short- and long-term efficacy are less clear. Stent implantation has added an important dimension to percutaneous re-vascularization strategies and has been shown to be an effective rescue device after acute or threatened vessel closure after failed PTCA. However, some studies with multivessel disease reported higher restenosis and repeat revascularization rates in patients treated with bare metal stents (BMS) than in those after surgical treatment. The introduction of drug-eluting stents (DES) indicating advantage over bare-metal stents in reducing the restenosis incidence and has narrowed the re-intervention gap between percutaneous coronary intervention (PCI) and coronary artery bypass graft (CABG) surgery in multivessel coronary artery disease (CAD). Additionally, performing multivessel PCI in a single index procedure has potential economic and social advantages. Here, we present our experience of the use of the Supralimus-Core sirolimus-eluting stent (SES) in patients with dual vessel CAD in an unselected real-world population. No study was especially designed to evaluate the safety and effectiveness of SES in patients with dual vessel disease. The study shows that, dual vessel Supralimus-Core SES implantation allows safe and effective treatment with low rates of TLF at one year follow-up in Indian population (Chandwani P, Prajapati J, Porwal S,et al. Evaluation of Clinical Outcomes in Patients Undergoing Dual Vessel Percutaneous Coronary Intervention Using Sirolimus-Eluting Coronary Stent System in India. Journal of Clinical and Diagnostic Research. 2015, Vol-9(2): 5-9).

BURKITT LYMPHOMA IN AN ADULT AIDS C2 FEMALE PATIENT (Abstract): We report the case of a 24- year-old female patient with stage C2 HIV infection presenting with complaints of fatigue and altered general status. She reported having amenorrhea for 4 months and pelvic pain. Her medical history was characteristic to lack of compliance with treatment, the viral load remaining high despite the prescribed intensive antiretroviral treatment. Intraoperatively we found: hypoplastic uterus of 30/20/20 mm in size and complete cystic transformation of the right ovary, the cyst size being of about 60/50 mm and the capsule intact. A right adnexectomy was performed. Immunohistological assessment about one month after surgery made the final diagnosis of Burkitt lymphoma. Studies show that an old HIV infection is associated with a higher risk for non-Hodgkin lymphoma (NHL) compared to patients with quite recent HIV infection. Conclusions: The reported case had high CD4 levels at the time of diagnosis and also a particular extranodal involvement, the right adnexa. The CD4 level was 198/mmc at the time the adnexal tumor was discovered, level reached after a long period of time of low CD4 levels and high viral load. **Keywords:** BURKITT LYMPHOMA, HIV INFECTION, OVARIAN TUMOR.

Burkitt lymphoma is a high-grade B-cell lymphoma classified as a non-Hodgkin lymphoma (NHL) (1). There have been described 3 main clinical types of Burkitt lymphoma: endemic, sporadic and immunodeficiency-associated (2). Immunodeficiency-associated Burkitt lymphoma is usually associated with HIV (human immunodeficiency virus) infection or occurs in post-transplant patients taking immunosuppressive drugs (3). Burkitt lymphoma can be one of the diseases associated with the initial manifestation of AIDS (acquired immune deficiency syndrome) (4).

As the other HIV-related non-Hodgkin lymphomas, Burkitt lymphoma has a poor prognosis, mainly due to the advanced stage of disease at the time of diagnosis, extranodal involvement and B symptoms (weight loss >10% of original body weight, night sweats and fever) (5). Patients are often included into the intermediate or high-risk group, based on the International Prognostic Index (IPI), which scores patients according to age (> 35 years), stage III or IV of disease, increased serum lactate

dehydrogenase (LDH), and extranodal involvement (6).

Burkitt lymphoma is the second commonest histological subtype of HIV-related lymphoma, after diffuse large B-cell non-Hodgkin's lymphoma (7). There is a clear correlation between the levels of CD4 cell count and the risk of developing NHL (5). It is thought that immune stimulation by HIV and reactivation of previous Epstein–Barr virus (EBV) infection due to defective T-cell surveillance, results in long-term stimulation and proliferation of B lymphocytes, ultimately leading to the development of HIV-related NHL (5).

CASE REPORT

A 24-year-old Caucasian female patient, diagnosed HIV-positive at the age of 11 and currently in C2 stage of HIV infection due to recurrent pneumonia, presented to our clinic in June 2013 complaining of abdominal pain, edema of the upper and lower limbs, fatigue and altered general status. The patient reported having amenorrhea for 4 months and the occurrence 3 month earlier of pelvic pain which tended to get worse.

Her *medical history* was characteristic for noncompliance to treatment (8), the viral loads remaining high despite the prescribed intensive antiretroviral treatment. Until August 2006, the CD4 counts were between 250-400 cells/mm3, but the viral load had never decreased enough to get close to undetectable levels, the lowest viral load that was ever recorded for the patient being 42.100 copies /ml. After Indinavir was withdrawn from the Romanian pharmaceutical market, she was prescribed another type of protease inhibitor, Saquinavir (SQV), associated with Ritonavir (RTV), Abacavir (ABC) and Didanosine (ddI). Despite the aggressive treatment the results were far from optimal, the viral load reaching a level of 2.500.000 copies/ml. In September 2009, the patient was prescribed Kaletra (Lopinavir and Ritonavir) together with Combivir, the combination offering a comfortable administration of only 6 cps/day, association known as highly active antiretroviral therapy (HAART), which covers the sanctuaries of HIV infection such as the ovarian stroma. Unfortunately the patient was noncompliant. At that time also appeared the idea of a possible virus resistance to therapy due to the high viral loads difficult to control therapeutically. As CD4 levels were low (123/mm3) while the viral load continued to be high (128.000 copies/ml), an antiretroviral drug-resistance test was performed in February 201.As the test showed Darunavir (DRV) to be the most effective the therapeutic scheme was changed, but until December 2011 the CD4 levels continued to decrease while the viral load increased. The patient admitted that sometimes she was not taking her medication for 10-14 days in a row.

Physical examination revealed: afebrility, slightly pale teguments, micropolyadenopathy in the inguinal, cervical, supraclavicular and axillary groups and normal respiratory tract and cardiovascular system evaluation. The patient complained of pain in the right iliac fossa. Gynecological examination showed a white vaginal discharge, confirmed a hypoplastic uterus, an enlarged right ovary of approximately 60/50 mm in diameter, with regular contour, sensitive to bimanual palpation.

Relevant *laboratory tests* included: anemia (Hb-8.6 g/dl), normal white blood count (WBC-5.6x10³/μL), low GR (2.7x10³/μL), low APTT (20.1/sec), normal

inflammatory markers (CRP and ESR), high uric acid (6.61 mg/dl), ALAT, ASAT (32 U/L and 46 U/L), Coli/ESBL in vaginal culture.

On the first night in hospital the patient was hyperpyretic (39ºC) and shivering; before the antibiogram for Escherichia Coli vaginal infection was available ampicillin was used as empiric treatment to which the fever having no response it was replaced with a 3rd generation cephalosporin that also proved to be ineffective. The next day the patient was referred to the Infectious Disease Hospital for further investigations and specific treatment.

After one month the patient was rescheduled for surgery. During this time the physical status had improved, amenorrhea, fatigue and the slight abdominal pain remaining the only complaints. Anemia was corrected with oral iron supplements (Hb-10.2g/dl), the patient presenting normal white blood cell count and moderate increase of inflammatory markers (CRP and ESR).

At surgery, after opening the peritoneal cavity the following were found: hypoplastic uterus (30/20/20 mm); the left adnexa appeared normal; the right adnexa: right ovary - complete cystic transformation, size of the cyst about 60/50 mm in diameter, intact capsule, with a regular contour and the right tube impossible to differentiate from the cystic tumor. Through the transparent cyst capsule a solid component of the tumor was noticeable. No lymphadenopathy was visible macroscopically in the pelvic area. Right adnexectomy was performed without damaging the cyst capsule. The next day the patient was transferred to the Infectious Disease Hospital for further care.

The macroscopic examination of the ovarian tumor made the diagnosis of solid ovarian tumor and cut sections of tumor revealed necrotic areas (Fig. 1, 2).

Fig. 1 Ovarian tumor - macroscopic aspect

Fig. 2 Ovarian tumor - macroscopic aspect

The histopathological examination revealed: proliferation of small tumor cells containing solid deposits, moderate pleomorphism, 1-3 macronucleoli, reduced or moderate cytoplasm, intensive mitotic activity and necrosis (Fig. 3, 4). The histopathological diagnosis was suggestive of small cell neoplasia or non-Hodgkin lymphoma (p T1a Nx Mx G3), the immunohistological examination performed about one month after surgery establishing the final diagnosis - Burkitt lymphoma (CD20, BCL6 and KI67 positive and CD3, Cytokeratin AE1/3 negative).

The patient was referred to the Regional Cancer Institute for further treatment. The protocol for Burkitt lymphoma required a CT-scan which was performed in Septem-

ber and showed supraclavicular, inguinal, and laterocervical micropolyadenopathies and a connective tissue mass located in the thymic compartment.

The routine follow-up 2 months postoperatively revealed: absence of pelvic pain, persistence of amenorrhea for 6 months, absence of digestive or urinary complaints, fully healed surgical scar. She was prescribed Duphaston 10 mg (2 tablets/day) for 7 days, followed by combined oral contraception starting on the first day of menstruation, in order to control the ovarian function.

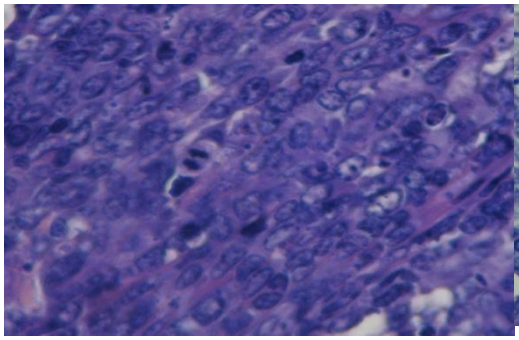

Fig. 3. Tumoral necrosis and intensive mitotic activity (HE x 40)

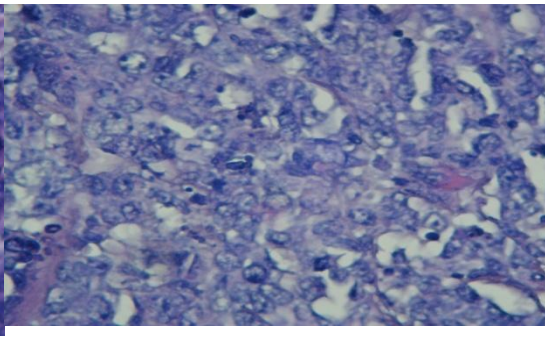

Fig. 4. Intense proliferation of small cells (1-3 macronucleols), reduced or moderate cytoplasm, containing solid deposits, moderate pleomorphism (HE x 20)

In October chemotherapy was initiated, using the fractioned protocol: course A consisting in the administration of cyclophosphamide, vincristine, adriamycin and dexamethasone, followed by course B including the administration of methotrexate and cytarabine, very well tolerated by the patient. The next scheduled appointment for chemotherapy is October 30. Until then the patient was prescribed Neupogen-1 (granulocyte colony-stimulating factor) subcutaneously for 10 days.

DISCUSSION

AIDS and immunosuppression create an adequate environment for the development of malignant tumors that are highly aggressive and generally have a poor prognosis (2). Studies show that an old HIV infection (≥8 years) is associated with a higher risk for NHL compared to patients with quite recent HIV infection (<4 years), our patient being diagnosed HIV positive since she was 11 years old (4). Prolonged immunosuppression is correlated with high CD4 count that is associated to a higher risk for NHL (CD4 >150 cells/μL), in our case the viral load was always high due to noncompliance with treatment (6).

The most common symptoms in AIDS-related lymphomas are the B type symptoms: fever, weight loss and night sweats (9), of which our patient presented only fever (5). Extranodal involvement is quite common, the most frequently affected being the gastrointestinal tract, liver or central nervous system, bone marrow included (3). Adnexal involvement is considered a rare extranodal site of the Burkitt lymphoma, especially in the case of a primary

extranodal involvement (3). Most patients are diagnosed with advanced-stage disease (1).

The treatment of Burkitt lymphoma in AIDS patients involves complex chemotherapy regimens (10). The HAART therapy, also administered to our patient, has been proven to determine a decline in CD4 cells count and associated with Neupogen determines less myelotoxicity and a better tolerance to therapy (10).

The prognosis in AIDS-related Burkitt lymphoma is poor and survival rates are of 2 to 24 months, evaluated according to CD4 T-helper lymphocyte count (<100 cells/μL), age (> 35 years), intravenous drug use and stage III or IV disease at the time of initial diagnosis (4).

CONCLUSIONS

The case we have reported had high CD4 levels at the time of diagnosis and a particular extranodal involvement. The CD4 level was 198/mmc at the time the adnexal tumor was discovered, level reached after a very long period of time of low CD4 levels associated with high viral load. The patient presented fever, but no weight loss or night sweats. She was diagnosed with stage I disease.

In our patient the prognosis was relatively favorable on specific treatment for AIDS and complex chemotherapy regimen administered for Burkitt lymphoma.

The particularity of this case is the primary extranodal involvement of the right adnexa, uncommon in Burkitt lymphoma.

PALLIATIVE TREATMENT OF MALIGNANT ESOPHAGOPULMONARY FISTULAS WITH COVERED SELF - EXPANDABLE METALLIC STENTS (SEMSS). A SINGLE CENTER EXPERIENCE(Abstract): **Aim:** The aim of our study was to determine the efficiency of SEMSs in patients with esophagopulmonary fistulas, regarding fistula closure,, enhancement of dysphagia scores and survival rates. **Materials and Methods**: Between January 2004 and June 2014, from a total of 133 patients who underwent stent placement procedures, 26 were diagnosed with esophagopulmonary fistulas. In 19 cases the fistulas were caused by esophageal carcinomas and in 7 cases by bronchogenic ones. 16 patients developed aspiration pneumonia, 3 lung abscess and 7 subclinical fistulas. **Results**: Complete fistula sealing occurred in 26 patients (100%). There were no immediate procedural complications except chest pain in 5 cases. After sealing of the fistulas and antibiotic treatment, pneumonia has regressed. After stent insertion, the dysphagic syndrome improved significantly (mean dysphagia scores decrease from 3.28 to 1.3 after stent insertion). The main goal of palliative therapy in patients with unresectable cancer and esophago-pulmonary fistulas is to close the fistulas, thus preventing the aspiration of saliva and food into the bronchus. Other goals include amelioration of dysphagia symptoms, maintenance of oral intake and improvement of quality of life. Ultimately covered expandable metal stents may increase survival rate as compared with other therapies. **Conclusions**: The endoscopic placement of covered SEMSs is the treatment of choice for malignant esophago-pulmonary fistulas. **Keywords**: ESOPHAGO-PULMONARY FISTULAS, SELF-EXPANDABLE METALLIC STENTS (SEMSs).

Patients with esophageal cancers often do not recognize any symptoms until late when the dysphagia is present and more than 75% of the luminal diameter is obstructed. At this time the tumor is often unresectable, either due to invasion of vital adjacent structures, or due to distant metastasis in liver/lungs. Esophago-pulmonary fistulas develop in patients with advanced esophageal and lung cancer and lead to continuous aspiration of saliva or food in the bronchial tree. Their development can be related to tumor invasion, laser treatment, radiation therapy or pressure necrosis caused by a previously placed stent (1).

The goals of palliative therapy in pa-

tients with unresectable cancer aim to ameliorate symptoms of dysphagia, treat complications such as esophago-pulmonary fistula, maintain oral intake, minimize hospitalization, relieve pain, eliminate reflux/regurgitation, prevent aspiration, and of course to improve the quality of life and to increase survival rates (2). There are multiple prospective case series using SEMSs for esophago-pulmonary fistulas reporting occlusion rates of 70-100% and complication rates between 10 and 30% (3).

Self-expanding metal stents (SEMSs) were first introduced for the treatment of esophageal stenosis in the early 1980 and nowadays are gold standard for palliation therapy (4). Esophago-pulmonary fistula is the only condition in which covered expandable metal stents certainly increase survival rates compared with other therapies (5). For persistent fistulas or recurrent fistula, placement of an airway stent may be additional palliative option. Multiple studies evaluate closure rates of fistulas and complications after stent placement. Most of them report complications between 10-30% and occlusion rates between 70-100% (6). Shin et al had a 80 % fistulas closure and a mean survival of 3 months (1-56 weeks) significantly longer in patients with complete fistula sealing compared with incomplete fistula closure (15.1 *vs.* 6.2 weeks, $p < 0.05$) (7).

MATERIAL AND METHODS

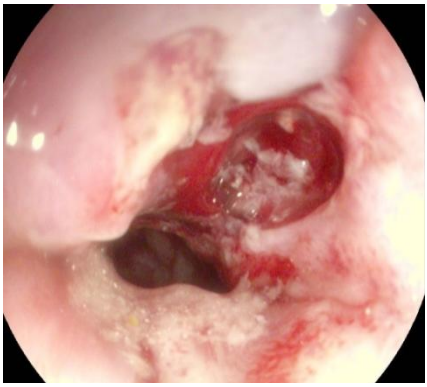
Between January 2004 and June 2014 a consecutive series of 133 patients with malignant dysphagia (86.5% men, 13.5% women), aged 46-86 years (mean 61.74 yrs) underwent stent placement under general anesthesia, using fluoroscopic control. Malignancy was established using upper endoscopic examination and biopsy in all patients.

In 84.3% of cases, the etiology of malignant dysphagia was intrinsic, due to esophageal cancer, while in 63.7% of the cases the etiology of malignant dysphagia was extrinsic due compression by bronchial cancer. A total of 26 of the patients with aero-digestive fistulas were identified, ages between 48 and 85 yrs. (mean 60.24 yrs.). In our group 73% of the fistulas were caused by esophageal primary lesion (6 located in upper third, 11 located in middle third, and 1 in lower third of the esophagus) and 27% by bronchogenic carcinomas. At the time of stent placement, 16 patients had aspiration pneumonia and 3 had lung abscesses visible on thoraco-abdominal scan. Seven patients had subclinical fistulas identified during stents placement, not visible on previous CT scan and not manifested clinically. From the 3 patients with lung abscesses, two had esophageal cancer and one had bronchogenic cancer. Only 4 women were diagnosed with fistulas, with a large majority of men. In one case at least 2 fistulas were observed. Only one case was associated with a preinstalled stent, a fistula being noticed close to the proximal opening.

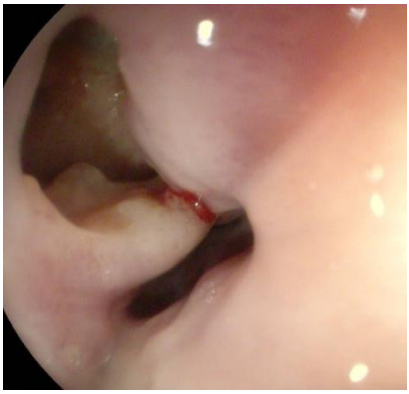
All patients were treated with successfully with a single covered expandable metallic esophageal stents. We used Self-expandable metallic stent (SEMSs) made of a nickel-titanium alloy (Nitinol) with partial polyurethane coverage (20 Ultraflex and 6 Wallflex). We used SEMSs with length between 70-150mm and diameters from 10 mm to 23 mm according to stenotic lesion and position of stricture.

While majority of patients were treated under general anesthesia with tracheal intubation, whenever a major fistula was suspected, we choose in favor of light sedation with topical anesthesia, in order to avoid

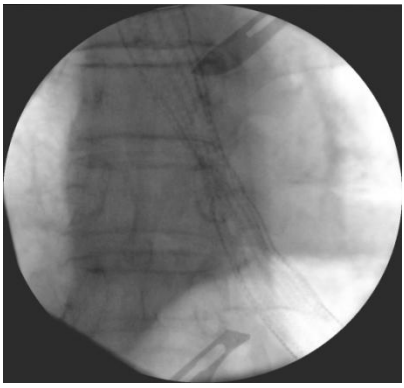
ventilation problems generated by the abnormal communication. An upper gastrointestinal endoscopy was performed to establish the upper limit of the esophageal stricture, and a radio-opaque skin marker was placed. Using endoscopic and fluoroscopic help (fig. 1), the guide wire was gently inserted through the esophageal stricture into the stomach. The stent introducer was inserted over the guide wire under fluoroscopic guidance and the stent deployed from the delivery system. In relatively large stenosis the endoscope may be passed and the lower limit marked. Stents are generally selected at least 4 cm longer than the stricture (2 cm above and 2 cm below the stricture). The uncovered portion of the partially covered stents allows for embedding and better anchoring of the stent. Fistula identification relative to stricture was essential, so that the covered part of the stent will cover it and seal the fistula tract.



Fistula caused by esophageal cancer



Fistula caused by bronchogenic cancer



Complete SEMSs deployment between radio-opaque markers

Fig. 1. Endoscopic and fluoroscopic aspects of fistulas

RESULTS

Stent placement was technically successful in 26 cases (100%), and there were no immediate postprocedural complications, with the exception of moderate chest pain in 5 cases. Complete fistula sealing resulting in resolution of aspiration symptoms (clinical success) was achieved in 26

patients (100%). Before stent placement all patients reported significant dysphagia, with a mean dysphagia score before stent insertion of 3.28. All patients were able to swallow well postprocedural with an overall dysphagia score of 1.3 (tab. I).

TABLE I

Dysphagia score was adapted from the Mellow-Pinkas dysphagia score

Dysphagia scoring scale
0 Able to consume a normal diet
1 Dysphagia with certain solid foods
2 Able to swallow semi-solid soft foods
3 Able to swallow liquids only
4 Unable to swallow saliva (complete dysphagia)

All patients died during the follow-up period (median survival 62.28 days; range 12-137 days) with earlier deaths for those with septic complications (pneumonia or pulmonary abscess). It is very difficult to estimate a benefit in survival, as the life expectancy with an untreated fistula and symptomatic aspiration can be days or weeks. We assume that our patients survived probably longer, but certainly with a better quality of live.

DISCUSSION

Esophageal stenting using SEMSs is nowadays the gold standard in the palliation of malignant dysphagia (10). SEMSs are clearly superior to rigid plastic prostheses in the management of unresectable obstructive esophageal cancers, and covered SEMSs are preferred to uncovered SEMS mainly because of lower rates of tumor ingrowth. Multiple complications caused by stent placement in esophageal malignancies have been described, and their frequency range from 10 to 30 % in most series (11). They are related to tumor location and tumor diameter, the presence or absence of the fistula or tumor shelf, use of concomitant chemo radiation (especially radiation which can minimize the tumor diameter), tumor vascularity, and, of course, diameter, length and design of the prosthesis itself. The most typical complications are described in the table below (tab. II).

TABLE II

Possible complications of esophageal self-expandable metal stents

Procedural Complications	Post-stent Placement Complications
Stent misplacement	Halitosis
Chest pain	Food impaction
Procedural infection	Over - growth/ In - Growth
Aspiration	Stent migration
Tracheobronchial perforation and pneumothorax	Tracheoesophageal fistula
Bleeding	Bleeding
	Gastroesophageal reflux disease / aspiration
	Infection and septic shock

Chest pain is typically observed following stent insertion, in all patients, with an intensity related to the degree of stricture (11). We reported only 5 cases with major

chest pain requiring antalgic medication for more the 24 hours, but we assume thoracic discomfort as a norm in all patients. We do not consider pain a complication unless it prolongs admission and may raise the possibility of subclinical perforation.

Stent migration is the single most important problem related to SEMS. While in some patients it is associated with food impaction due to lack of dietary compliance, in most cases a single factor cannot be pinpointed. Strong esophageal contraction can dislodge a stent, while chemo-radiation induced shrinking will make the stent loose. We did not encounter major procedure related complications in our series. While migration is not unusual this was not a significant event in the series. There was one stent migration into the stomach with recurrent dysphagia requiring another stent placement. Endoscopy identified the first stent in the stomach and decided to abandon it as removal can be very difficult and the typical life expectancy of these patients does not warrant a risky retrieval procedure (12). In one case, the tracheo-esophageal fistula was secondary to pressure necrosis by a previously placed stent, so a second stent was deployed inside the first one with excellent result.

The overall results show that SEMSs are very useful for symptom palliation in patients with unresectable or metastatic esophageal cancer and much more so in patients with aero-digestive fistula.

Survival in these cases is very short and without a method for fistula sealing one can expect to survive days or weeks. SEMS are excellent for aero-digestive fistula sealing which is achieved in all patients immediately and the major benefit is in the quality of life.

CONCLUSIONS

Esophagopulmonary fistulas are life-threatening complications, so complete closure of fistulas is the main aim of palliative treatment. The risk of septic shock is higher in patients with lung abscesses. The median survival in our series (~ 62 days) is within the range reported by others (40 to 110 days) but the benefit should not be evaluated in survival per se, but in the quality of life, reflected in the ability to swallow and feed.

Recurrent dysphagia due to overgrowth / in growth tumor is frequently observed in uncovered SEMSs and almost never in partially covered stents. However we recommend to our patients a semi solid diet, followed up by carbonated beverages to avoid food impaction. Usually, recurrent dysphagia is secondary to stent migration in noncompliant patients to regime restrictions.

The endoscopic placement of covered SEMSs is the treatment of choice for malignant esophago-pulmonary fistulas.

NEWS

A NEW COMPOUND FROM *CASSIA AURICULATA* WITH ANTI-PROLIFERATIVE EFFECT AGAINST COLON ADENOCARCINOMA

Cassia auriculata (*Caesalpinaceae* family) is one of the most common Asian medicinal plants. It is used in traditional medicine for the treatment of diabetes, skin problems or eye infections. Extracts from flowers, seeds and leaves possess anti-diabetic, hepatoprotective and emollient effects. A new compound, 4-(4-chlorobenzyl)-2,3,4,5,6,7 hexahydro-7-(2-thoxyphenyl) benzo[h][1,4,7] triazecin-8(1H)-one, was isolated from the leaf ethanolic extract. After structure elucidation, the compound was tested for its anti-proliferative effect against human colon cancer HCT15 cell line. The MTT assay showed that the cell viability was inhibited by 50% at a dose of 25 µg/mL after 48 h treatment. In addition, the new compound induced apoptosis at 25 and 100 µg/mL as revealed by propidium iodide staining protocol. Lactate dehydrogenase assay confirmed the cytotoxic potential of this compound. The results proved that the new isolated compound from *Cassia auriculata* leaves possess anti-proliferative effects and it is a promising compound for the treatment of colon adenocarcinoma (Esakkirajan M, Prahbu NM, Arulvasu C, Beulaja M *et al*. Anti-proliferative effect of a compound isolated from *Cassia auriculata* against human colon cancer cell line HCT 15. *Spectrochim Acta A* 2014; 120: 462-466).

RETROMOLAR TRIGONE – OROPHARYNX JUNCTION MALIGN TUMOR SURGERY: TRANSMANDIBULAR VERSUS ORAL APPROACH (Abstract) **Aim**: This study proposes a new approach to a borderline pathology between Otorhinolaryngology (E.N.T.) and Oral and Maxillofacial Surgery (O.M.F.), the malignant tumors of the oropharyngeal and retromolar trigone junction. **Material and Methods**: 52 cases of retromolar trigone and oropharynx malign tumors were solved in the ENT department of "St. Spiridon" Universitary Hospital Iasi between 2012 and 2014. All patients were males, 35-64 years old, in different TNM stages. The novelty stands in the multidisciplinary approach, with an operating team consisting of both E.N.T. and O.M.F. surgeons, which joined their knowledge and expertise in order to offer a better treatment for the patient. *Human Papilloma Virus* (HPV) infection has been known as a trigger factor in head and neck cancers. The connection between HPV infection and malignant tumors of the oropharyngeal – retromolar trigone junction, together with the other traditional risk factors (smoking, alcohol, stress and sexual behavior) are involved in the therapeutic protocols, improving the life quality, the survival rate and reducing the treatment costs. **Results and discussion**: Excision of the malignant tumors at the level of the junction between the oropharynx and retromolar trigone often requires repairing the tissular defects that remain using different flaps. Postsurgical mecanotherapy (physiotherapy) under the surveillance of an experienced physiotherapist is also needed for a complete recovery. **Conclusions**: This therapeutical protocol aims to assure a better life quality for the patients, with a faster postsurgical recovery and social reinsertion by reducing the healing time of the areas affected by inflammation and necrosis generated by the neoplastic process.
Keywords: MALIGNANT TUMORS OF THE OROPHARYNGEAL AND RETROMOLAR TRIGONE JUNCTION; ORAL APPROACH; TRANSMANDIBULAR APPROACH.

Access to bulky tumors of the oral cavity and most tumors of the oropharynx via the open mouth is often difficult and inadequate (1, 2, 3).

In the past, segmental mandibulectomy was routinely performed for resection of large primary tumors of the oral cavity or oropharynx. In many instances the mandible was neither clinically, nor radiographically involved in the tumor but was

sacrificed to gain access to the oral cavity and oropharynx.

Division of the mandible instead of resection provides equally good exposure of the interior of the oral cavity and permits a satisfactory monobloc resection of the primary tumor, often in continuity with neck dissection if is indicated (3, 4, 5, 6).

A paramedian mandibulotomy would be ideal to gain access to the oral cavity as it offers all the advantages of a median mandibulotomy and avoids disruption of the genial muscles, the only muscle requiring division being the mylohyoid on one side. Covering the defects after the excision with different skin flaps is indicated for stage III tumors (6, 7, 8).

Establishing a direct connection between Human Papilloma Virus (HPV) infection associated with other external factors (alcohol, smoking, emotional stress) and oropharyngeal malignant tumors is important in setting the most suitable therapeutical plan for the patient. Finding the exact type of HPV that colonizes the oropharynx for our region could lead to a vaccine similar to that for the cervix cancer (10).

An early diagnosis and prophylactic measures (proper hygiene, advising against smoking and alcohol consumption, sexual education) can improve the survival rate and life quality of these patients and will reduce the treatment costs (11).

MATERIAL AND METHODS

Fifty-two cases of retromolar trigone and oropharynx malign tumors were solved in the Ear, Nose and Throat (E.N.T.) department of "St. Spiridon" Universitary Hospital Iasi between 2012 and 2014. All of them were male patients between 35 and 64 years old with carcinomas in different TNM stages. The main surgical approaches were: 1. Transmandibular mandibulotomy, mandibulectomy; 2. Oral approach: classical surgery or CO_2 laser. In all cases we management of the neck lymph nodules and submandibular gland was considered.

The choice of approach depends on the size/location of the tumor, the chosen method of reconstruction and whether a concomitant neck dissection is being planned. Oral approach was performed in 46 cases and is indicated when the tumor is limited to the tonsilar pillars, one half of the soft palate, uvula, palatine tonsil, retromolar trigone (stage I–II tumors) and also for tumors located only at the base of the tongue. Oral approach is indicated when the tumor is limited to the tonsilar pillars, one half of the soft palate, uvula, palatine tonsil, retromolar trigone (stage I–II tumors) and also for tumors located only at the base of the tongue. Transmandibular approach is used if both anatomical segments are affected. It is indicated for stage III tumors that need ganglia extirpation and, if necessary, covering of the defect with skin flaps (6, 13, 14, 15).

Transmandibular approach was performed in 6 cases and is used if both anatomical segments are affected. It is indicated for stage III tumors that need lymph nodules extirpation and, if necessary, the defect is covered with skin flaps. Most surgeons agree that resection should be reserved for those oropharyngeal lesions with well-defined borders. When the margins of the primary tumor blend imperceptibly with the adjacent mucosa or when multifocal disease is present, radiotherapy is usually preferable. We also check the presence of HPV infection which has been known as a trigger factor in head and neck cancers. Establishing whether the patient is

infected with HPV and has other risk factors like smoking, alcohol, stress and abnormal sexual behavior is necessary for deciding the surgical protocol, improving the quality of life and the survival rate (10).

Patient selection for a mandibulotomy approach requires accurate assessment of the proximity of the tumor to the mandible. In some patients who had painful lesions or trismus, examination under general anesthesia was necessary. Ideally, there should be a rim of normal tissue between the tumor and the mandible, but the line of excision was occasionally carried to the alveolus or the anterior border of the ramus if the tumor involved the anterior tonsillar pillar and approached the periosteum (6, 8, 12, 16).

CASE 1

Male, 50 years old, hospitalized in the E.N.T. department of "Sf. Spiridon" Hospital Iasi for disphagia, trimus, pain and lymph nodules at the level of the neck which appeared a couple of months prior to the examination.

Local examination: well delimited right laterocervical tumefaction of about 5/4 cm, of hard consistency, mobile on the deep and superficial fascias, covered by normally colored skin. Oral cavity exam: infiltroproliferative process set at the level of the right tonsil with infiltration of the anterior tonsilar fold and inferior extension to the right one third of the tongue and the right glossotonsilar sulcus and retromolar trigone (fig. 1).

The CT exam shows tumoral appearance at the level of the right palatine tonsil of 33/24/33 mm with the following limits: 1. Lateral - the pterigoidian muscle; 2. Anteromedial - the base of the tongue; 3. Posterior - the pharyngeal constrictor muscle; 4. Superior – plane through the soft palate; 5. Inferior – plane through the epiglottis (fig. 2), right superior jugular adenopatic block of 38/32/47 mm with mass effect over the internal jugular vein and the common carotid artery and multiple small laterocervial adenopathies (fig. 3).

We performed right extended tonsillectomy and excision of the retromolar trigone by endoral approach, together with right radical lymph node dissection (fig.4, 5, 6).

Anatomopathological exam: moderately differentiated non-keratinizing squamous cell carcinoma, with infiltration of the striated muscle fascicles.

Fig. 1. Tumor at the level of retromolar trigone and right tonsil

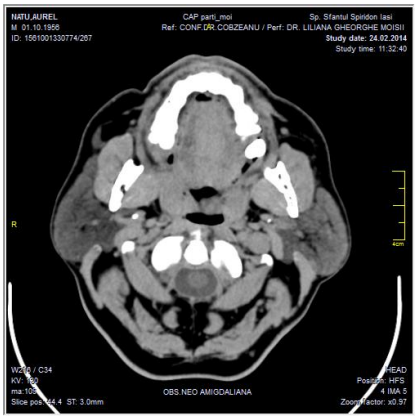

Fig. 2. The CT exam shows a tumor at the level of the right palatine tonsil.

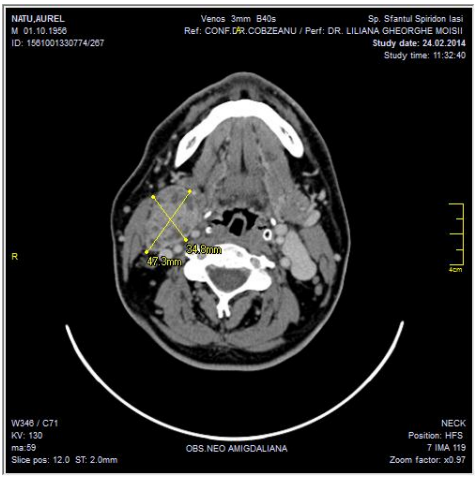

Fig. 3. Right superior jugular adenopatic block

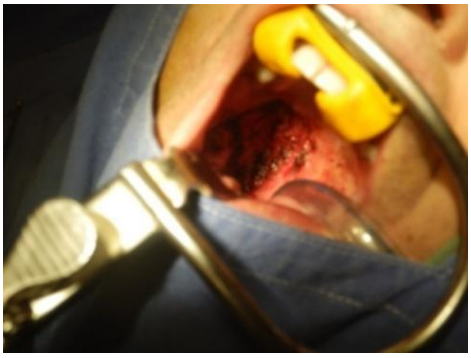

Fig. 4. Palatine tonsillectomy by endoral approach

Fig. 5. Lateral functional neck dissection

Fig. 6. The excised specimens

The surgical treatment was followed by chemo and radiotherapy. The 1 year follow-up showed quasi-normal deglutition and phonation, with no signs of local recurrence.

CASE 2

Male, 53 years old, hospitalized in our department for a tumor at the level of left retromolar trigone and palatine tonsils, with extension to the anterior palatine fold and left cervical lymph nodules in groups II and III.

Local exam: well delimited left latero-cervical tumefaction, of 5/3 cm, of hard consistency, mobile on the deep and superficial fascias, covered by normally colored skin. Oral cavity exam: infiltro-proliferative process set at the level of the left tonsil, with infiltration of the anterior and posterior tonsilar fold and inferior extension to the left one third of the tongue and the left glosso-tonsilar sulcus (fig. 7). CT exam: oropharynx asymmetry with the thickening of the left lateral wall and left jugulo-carotidian adenopathy that has mass effect on the internal jugular vein (fig. 8).

Transmandibular approach was used, with inferior labial middle line incision which continued to the mental foramen form the opposite side of the osteotomy.

The left palatine tonsil and the retromolar trigone were excised and the defect was covered with a temporo-parietal fascial flap. Neck dissection was performed with resection of lymph nodules and submandibular gland. Anatomopathological exam: poorly differentiated non-keratinizing squamous cell carcinoma. The 6 months follow-up showed quasi-normal deglutition and local aspect, with no signs of local recurrence (fig. 9, 10, 11).

DISCUSSION

If the mandible is resected, the surgical approach is done through the lower lip, on the midline, all the way down to the labiomental groove and then curbing in the opposite direction of the osteotomy.

The osteotomy is done paramedially on the side of the lesion, between the canine and the premolar, in front of the mental foramen in order not to damage the inferior alveolar nerve. Patient selection for a mandibulotomy approach requires accurate assessment of the proximity of the tumor to the mandible. In some patients who had

painful lesions or trismus, examination under general anesthesia was necessary.

Ideally, there should be a rim of normal tissue between the tumor and the mandible, but the line of excision was occasionally carried to the alveolus or the anterior border of the ramus if the tumor that involved the anterior tonsillar pillar approached the periosteum

The gingival and lingual mucosa is then dissected from the premolar all the way to the third molar tooth, followed by detaching the mylohyoid muscle from the bone. The mandibulotomy is never made in the middle because it produces functional and statical dysfunctions at the level of the tongue by denervation and displacement of the structures. This ensures the preservation of the inferior alveolar neurovascular bundle. The periosteal vasculature remains viable on the external side of the mandible. Osteosyntesis with plates is preferred.

For esthetical reasons, the inferior medial labial incision must be arched through the labiomental groove, opposite the mandibulotomy, so that the bone incision does not overlap with the soft tissue incision. In general, these defects are very complex, affecting both the aesthetics and the functionality of the area (mastication, deglutition, phonation).

Different methods are available that range from primary closure and healing by secondary intention for the smaller defects to the use of local, myocutaneous and free microvascular tissue transfer flaps. The flaps must be thin and wide because the area that needs to be covered is large. Temporoparietal fascial flaps, Bichat's lobule pedicle flaps and radial free flaps are preferred for covering the defects (6, 13, 14).

Neck dissection has been previously performed. Conventional unmodified radical neck dissection was employed in patients who were staged N1 on admission. At patients who had no evidence of cervical metastasis, we perform elective neck surgery, with conventional radical neck dissection, modified radical neck dissection, supraomohyoidian neck dissection or suprahyoidan neck dissection. We believe that paramedian mandibulotomy in combination with postoperative radiotherapy, when appropriate, offers an attractive alternative to high dose radiotherapy alone in patients with oropharyngeal and retromolar trigone junction carcinoma. Transmandibular approach gives the possibility of excising the lesion and covering the tissue defect with a temporoparietal flap (6).

Three main issues that result from curative surgical treatment appeared in our statistics: 1. Sequelae or complications of the treatment in 3 cases; 2. Functional deficits or interference of physiological functions in 5 cases; 3. Recurrent/persistent disease in 2 cases.

All of the patients were solved by surgical methods and were seen back 12-14 days after discharge and instructed on diet, swallowing therapy, physical therapy of the neck and shoulders and voice therapy.

CONCLUSIONS

All the patients included in our study, with tumours at the level of the oropharynx and retromolar trigone were early diagnosed. Otherwise the survival rate decreased significantly.

If the tumoral process is extended into the retromolar trigone, the middle of the tongue, the base of the tongue or valeculas we highly recommend to perform a computed tomography (CT scan) to precisely evaluate the extension of the lesions. A

mixed operating team formed by ENT and OMF surgeons should perform the surgery.

For stages I-II, either surgical treatment or radiotherapy can be applied, with similar results.

Antibiotic therapy prior surgery is essential for stopping tumoral infection, a problem in the pharyngeal area.

Oral approach is indicated when the tumor is limited to the tonsilar pillars, one half of the soft palate, uvula, palatine tonsil, retromolar trigone (stage I–II tumors) and also for tumors located only at the base of the tongue, the transmandibular approach being indicated in advanced stages (stage III-IV tumors).

Patients infected with a high-risk type of HPV have better prognosis after surgery than those with different phenotypes or without HPV.

STUDY OF AUTOPHAGY-RELATED PROTEIN LIGHT CHAIN 3 (LC3)-II EXPRESSION LEVELS IN THYROID DISEASES

Thyroid cancers are the most common malignant tumors of the endocrine system. The survival-promoting role of autophagy in tumor cells has been received universally. The aim of the study was to explore autophagy-related protein light chain 3 (LC3)-II expression levels in thyroid diseases including papillary thyroid cancer. A total of 45 thyroid samples, including 19 samples of papillary thyroid cancer, 7 samples of nodular goiter, 8 samples of Hashimoto thyroiditis and 11 samples of normal thyroid tissue resected during surgery, were selected and divided into pathological groups using light microscope. Levels of autophagy-related protein LC3-II in four different types of thyroid tissue were tested through Western blot. SPSS19 software was utilized to analyze the research data statistically. LC3-II protein levels in papillary thyroid cancer tissues were lower than that in normal thyroidtissues significantly ($P<0.05$). Compared with normal thyroid tissue, expression levels of LC3-II protein were higher in samples of Hashimoto thyroiditis and nodular goiter ($P<0.05$). Multi-factor analysis of variance showed that there was no significant correlation between LC3-II protein levels and patients' gender of thyroid cancer, while there was significant variation between patients with and without lymph node metastasis. Compared with patients of thyroid cancer without lymph node metastasis, the level of LC3-II protein was lower in patients of thyroid cancer with lymph node metastasis ($P<0.05$). Detection of LC3-II protein expression levels in thyroid diseases may contribute to the clinical diagnosis and provide theoretic basis for the therapy. IMMUNE FETAL HYDROPS-A SEVERE FORM OF RH ISOIMMUNIZATION (Abstract). The prevalence of pregnancies with Rh isoimmunization decreased to about 0.6% of all cases due to anti-D immune globulin prophylaxis. Rh incompatibility or Rh isoimmunization pregnancies must be monitored by serial measurements of titers of maternal Rh antibodies and, if possible, by serial Doppler evaluation of peak systolic velocity in the middle cerebral artery. Nowadays, for the detection of fetal blood group and Rh we can use techniques which identify free fetal DNA in maternal plasma. We report the clinical case of a 35 years old woman, admitted to our clinic after not being able to perceive active fetal movement. She proved to be Rhesus negative, with a pathological obstetrical history and through ultrasound examination, the diagnosis of fetal hydrops was established. The presence of fetal hydrops determines the viability of a small percentage of about 11%, and the long-term prognosis of these children is burdened by the need of repeated transfusions to combat the inhibition of erythropoiesis. Our report highlights the importance of early diagnose and precise antibody monitoring, to provide proper management and prophylaxis. **Keywords:** IMMUNE FETAL HYDROPS, RH ISSOIMMUNISATION, DOPPLER ULTRASOUND.

Fetal hydrops is defined as an abnormal fluid collection in two or more areas of the fetal body, such as ascites, pleural effusion, pericardial effusion and skin edema (1, 2). The etiologies of fetal hydrops are classified as immune or non-immune hydrops. Immune hydrops develops due to fetal hemolysis mediated by circulating maternal antibodies to fetal red blood cell antigens. Recent advances in obstetric and neonatal medicine achieved significant improvements in diagnosis, prevention and management of fetal hydrops. Specifically, immune hydrops has been decreased by routine screening and prophylaxis of Rhesus iso-immunization (1,3). Non-immune hydrops can result from many causes including cardiac abnormalities (structural anomalies, cardiomyopathies and arrhythmias) and non-cardiac anomaly, aneuploidy, congenital infection, twin-to-twin transfusion syndrome, chorioangioma and other conditions. Different types of infections, such as toxoplasmosis, cytomegalovirus, herpes simplex virus, syphilis, and Parvovirus B19 are the most common congenital infections that cause fetal hydrops. But, the precise cause of non-immune hy-

drops remains unknown in 15% to 25% of cases (3, 4), with an unchanged incidence (6) and a high mortality rate (4, 6, 8).

Fetal hydrops is easily recognized by ultrasound examination, during which we should try to figure out the etiology and nature of the hydrops, including the location, number and amount of fluid collections, amniotic fluid index, placental thickness, fetal echocardiography and Doppler velocimetry. However, there is limited information regarding the association between the ultrasound findings and perinatal outcomes of fetal hydrops, specifically neonatal mortality (10, 12, 13). Therefore, the aim of this case report is to show the clinical characteristics of fetal hydrops and to find out whether the antenatal ultrasound findings, especially the location or number of fluid collection sites, are associated with adverse perinatal outcomes.

CASE REPORT

We report the case of a pregnant woman 35 years old from the rural environment that presents to the hospital in emergency for the lack of perceiving of the active fetal movements.

The anamnesis highlights the fact that she didn't followed the prenatal follow-up, she was Rhesus negative (her partner was Rhesus positive) and she had a titer of serum anti D antibodies of 1/32.

Her obstetric history consists of 2 normal birth of two healthy children of 3000 and 3500g and 2 spontaneous abortion at gestational age of 2 months for which she didn't followed the anti-D immune globulin prophylaxis.

At admission to the hospital her blood pressure was 160/100 mm Hg, and she complained of epigastric pain that irradiates to her right shoulder (tab. I).

TABLE I

Patient biochemical profile

Hb= 9.9g/dl Ht = 29.6% PLT = 200000/ mm³ WBC = 12100/mm^3	Glucose = 70mg/dl FIBRINOGEN: 528mg/dl ESR = 12 mm/h
INR = 0.97 Ind Q = 102% TIMP Q = 12.7/s MARTOR = 13/s APTT = 40.6/S PDF = 1600-3200 ng/ml LDH = 658 U/L	Creatinine = 0.85mg/dl Urea = 19mg/dl Uric acid = 7.67mg/dl TGP = 64 U/L TGO = 106 U/L Group Rh: AII negative.
Direct urinary exam: Albumin 100 mg / dl; ketones: traces; bilirubin ++; nitrites present; microbial flora present; leukocyte cylinders present.	

Ultrasound reveals the diagnosis of hydrops fetal: a single living fetus of 29 weeks three days with an abdominal circumference (AC) of 39 weeks 3 days; Oligoamnios; Placental thickness 100mm gr I (fig. 1a); Scalp edema 17mm (fig. 1b); IR ACM-0.70; IR AO-0.61; ICP> 1.14; severe fetal ascites (fig. 1c); bilateral pleural effusions (fig. 1d); cardiomegaly.

At approximate 24 h after the admission, we decided to perform caesarean section for the diagnosis: VG IIIP 28 weeks of pregnancy, single living fetus, cranial presentation, intact membranes, Imminent premature birth,

Rh isoimmunization, Immune fetal hydrops, Preeclampsia, Acute Fetal Suffering.

We extracted a newborn who didn't respond to resuscitation (Apgar score = 0), female, weight 2,040g (fig. 2). The placenta weighed ~ 1,700g.

Fig. 2. Severe fetal ascites – clinical aspects: a. Edema and distention of abdomen due to ascites; b. coarse facial features, hypertelorism, depressed nasal bridge, anteverted nostrils, long philtrum, brachycephaly.

DISCUSSION

The diagnosis and management of fetal hydrops have improved in recent years with advances in prenatal diagnostic and thera-

peutic interventions, together with the advances in neonatal intensive care. However, fetal hydrops is still associated with a high mortality rate.

In recent years, most newborn infants with this pathology were classified as non-immune fetal hydrops as the proportion of infants with immune fetal hydrops decreased to 10% due to the use of anti-D immunoglobulin prophylaxis, intrauterine transfusions, and close follow-up of the pregnancies with Rh-isoimmunization in developed countries. The etiology of fetal hydrops is known to be significantly associated with prognosis (4, 10).

With the recent advances in prenatal ultrasound and the increase acceptability of the method, fetal hydrops is almost always diagnosed by antenatal ultrasound. Therefore, we presented a case of immune fetal hydrops due to the Rh incompatibility, which was diagnosed incidentally by an antenatal ultrasound, presenting fetal ascites, pleural effusion, scalp edema and placental thickness, with a poor perinatal outcome.

According to various literature sources, the presence of pleural effusion was a poor prognostic factor of fetal hydrops (11). The most important findings in different studies was that the number of fluid collection sites was highly correlated with neonatal outcome including low Apgar score and neonatal death, as it was in our case. A similar result was found in a recent study by Kim et al. who studied 43 women with non-immune fetal hydrops. They developed an 'ultrasonographic severity scoring of non-immune hydrops (USNIH) defined as a total number of abnormal fluid collections. Perinatal mortality rate, defined as stillbirth or neonatal death ≤28 completed days after birth, was significantly higher in cases with USNIH of ≥3 than in those with USNIH of 2 (13,14).

Usually, in early stages, the doppler velocimetry is one of the most important predictor factors for fetal or neonatal mortality in various fetal compromise conditions, including fetal hydrops (11, 12, 13). The pattern of abnormal Doppler velocimetry indices may depend on different cause of fetal hydrops. For example, abnormal umbilical artery Doppler or MCA pulsatility index reflects fetal hypoxia, abnormal MCA peak systolic velocity may reflects fetal anemia, and abnormal ductus venosus Doppler occurs as a result of fetal cardiac decompensation (15). In our case, Doppler velocimetry wasn't required, considering the advanced form of the disease, with multiple effusion sites.

CONCLUSIONS

These results from different studies, taken together with our clinical case, may suggest that the number of fluid collection sites is the strongest antenatal ultrasound risk factor of prediction the poor outcome in fetal hydrops, as we illustrated in this presentation

This case underlines the importance of enforcing anti-D immune globulin prophylaxis when necessary, mainly to avoid the consequences of isoimmunization in Rhesus negative mothers that can result in unfavorable outcomes for both the mother and the fetus.

TREATMENT ALGORITHM FOR THE MANAGEMENT OF COMPLICATIONS CAUSED BY PERMANENT FILLERS IN THE FACE

Despite recent developments in the usage of resorbable substances such as hyaluronic acid, non-resorbable substances are still used to enhance soft-tissue volumes. Inflammatory reactions are frequent and disabling. Therapeutic options are nonspecific. A study was conducted as a review of 219 consecutive patients referred between 2006 and 2013. Screening was made with an ultrasound soft-tissue examination and the lesions were classified as either cystic or infiltrating, infiltrating patterns were treated intralesionaly withan 808-nm diode laser laser treatment alone, cystic lesions were also drained through stabwound incisions. In 62 percent the lesions disappeared completely, Partial improvement wasobtained in 30 percent, whereas 8 percent discontinued the treatment. A systematic approachis proposed, based on 7 years of experience, with an overall improvement rate of 92 percent (Cassuto D, Pignatti M, Pacchioni L, Boscaini G, Spaggiari A, De Santis G. Management of Complications Caused by Permanent Fillers in the Face: A Treatment Algorithm. *Plastic and Reconstructive Surgery* 2016; 138(2): 215-227).

METASTATIC CARCINOID TUMOR- ATYPICAL PRESENTATION

Alina Pleşa, Emanuela Sarca, Roxana Maxim
University of Medicine and Pharmacy "Grigore T. Popa"- Iaşi
Faculty of Medicine
Department of Medical Specialties (I)

METASTATIC CARCINOID TUMOR - ATYPICAL PRESENTATION (Abstract): Carcinoid tumor is a slow-growing type of neuroendocrine tumor, originating in the enterochromaffin cells and secreting mainly serotonin. Neuroendocrine tumors (NETs) are found throughout the intestinal tract, the appendix and terminal ileum being the most common locations, and are classified by site of origin and by degree of differentiation, with well-differentiated lesions representing those tumors formerly referred to as carcinoid tumors. The clinical symptoms are characterized by flushing, diarrhea, abdominal pain, and/or bronchial constriction and occur almost exclusively in patients with liver metastases due to the release of bioactive peptides and amines directly into the systemic circulation. We report the clinical, serological and histological diagnosis of a 67-years-old male patient with congestive heart failure secondary to carcinoid heart disease in the context of liver metastases of an ileum carcinoid tumor. **Keywords**: CARCINOID SYNDROME, HEART DISEASE, METASTATIC LIVER DISEASE, SEROTONIN.

Neuroendocrine tumors (NETs) are a very heterogeneous group arising from the neuroendocrine cells, and include carcinoid, non-carcinoid gastroenteropancreatic tumors, catecholamine-secreting tumors (phaeochromocytomas, ganglioneuroblastomas, paragangliomas, and neuro-blastoma), medullary carcinoma of the thyroid, chromophobe pituitary tumors, small cell lung cancer and Merkel cell tumors. The different NETs may be divided into functioning and non-functioning tumors (1).

The carcinoid syndrome occurs in approximately 10% of NETs and becomes manifest when vasoactive substances from the tumors, such as serotonin as well as several other chemicals, enter the systemic circulation escaping hepatic degradation (2, 3).

This particular type of syndrome is often encountered when metastatic lesions are found spread throughout the liver or they develop from the bronchi. The clinical properties are characterized by flushing (63%–94%), diarrhea (68%–84%), abdominal pain (10%–55%), telangiectasia (25%) and bronchial constriction (3%–19%) (4, 5). High levels of vasoactive substances released from hepatic metastases can cause, in 10-20% of patients with carcinoid syndrome, the appearance of lesions that compromise the integrity and functionality of the endothelium and cardiac valves causing heart failure (6, 7).

CASE PRESENTATION

A 67-year-old man was admitted for

watery diarrhea, abdominal discomfort and shortness of breath. He had been having loose stools for 5 years, with 3 to 4 bowel movements per day, progressing over the previous 2 months to 4-5 large volume watery stools daily, including nocturnal stools. Abdominal cramps preceded these episodes and were partially relieved by bowel movements. He noted no blood or oil in the stool.

On examination, the patient was alert and oriented. His body mass index was 17. The temperature was 37.2°C, blood pressure 95/65 mm Hg, pulse up to 100 beats per minute and regular, respiratory rate 19 breaths per minute, and oxygen saturation 99% while he was breathing ambient air. The scleras were anicteric, and the oropharynx had no ulcers or lesions. The neck was supple and without jugular venous distention.

Further clinical examination revealed a diffuse rash characterized by fixed pink patches on his scalp, trunk and limbs that became red and pruritic when scratched or exposed to sun and heat and facial flushing, brought on by exertion or strong emotion.

The abdomen was slightly distended, depressible and diffusely painful with a painless, firm, nodular hepatomegaly of 6 finger-widths. Splenomegaly was not noted. Brown stool was negative for occult blood. The neurologic examination was unremarkable.

Apparently, he was diagnosed 20 years ago with idiopathic liver disease and multiple hepatic nodular areas spread throughout the liver which were recorded and measured periodically to see any signs of growth. They maintained relatively stable in size over the last few years.

Six months prior to admission the patient underwent major cardiac surgery to replace the aortic and mitral valve, because of severe aortic stenosis and mitral regurgitation with favorable postsurgical outcome. After surgery, he was encouraged to seek gastroenterological advice for liver distress and intestinal discomfort.

On admission, the patient recalls he had had multiple similar episodes during the previous 5 years, with flushing, hypotension and mild diarrhea, but he managed to avoid seeking medical care. The symptoms, which were usually provoked by physical exertion, mental stress, or intense emotion, lasted up to 2 hours.

The ultrasound performed in our clinic confirmed the presence of numerous nodular areas spread throughout the liver which were suggestive of metastatic liver disease (fig. 1).

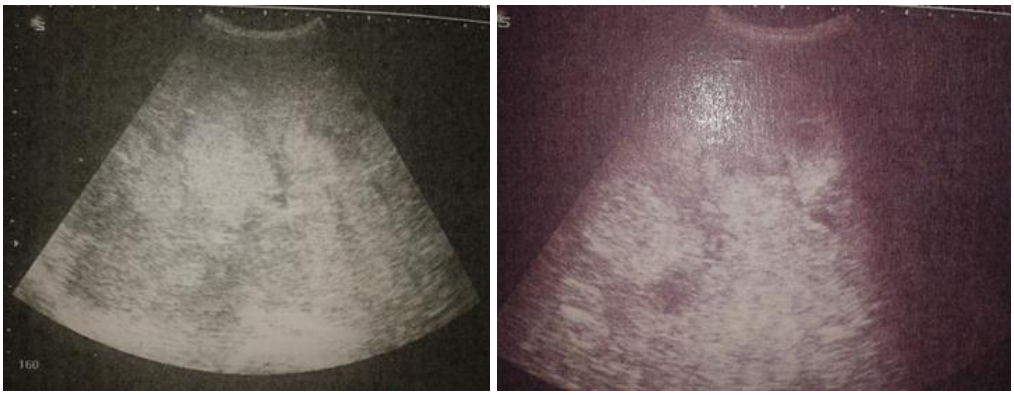

Fig. 1. Liver ultrasound: multiple hyperechoic nodules

Abdominal CT scan showed multiple hepatic masses, the largest was 10 cm in diameter and another mass located in the mesenteric region approximately 40 mm in diameter relatively well defined which needed additional tests to establish its nature.

Endoscopic video capsule was performed and it showed multiple irregular masses located in the proximal jejunum and ileum protrusive in the lumen and covered by normal looking mucosa, with visible vascular pattern but with no obstructive potential (fig. 2).

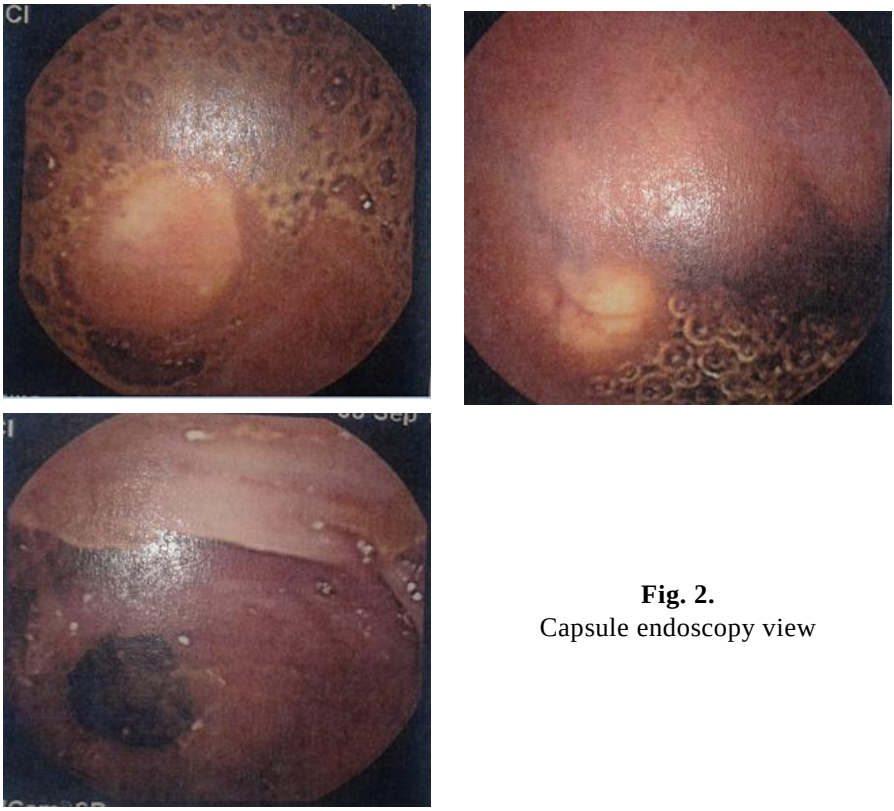

Fig. 2.
Capsule endoscopy view

Adding all the pieces of the puzzle, the clinical presentation (flush, diarrhea, low blood pressure), metastatic liver disease, intestinal tumor and heart disease the diagnosis of carcinoid tumor became obvious.

Serological tests including urinary levels of 5-hydroxyindoleacetic acid (5HIAA), serotonin (Ser) levels and chromogranin A concentration (Cg A) were performed and high levels of these parameters confirmed the diagnosis (tab. I).

TABLE I
Laboratory findings

Parameter	Value
Chromogranin A	22064µg/L
Urinary excretion of 5-HIAA.	148.5 mg/24h
Serotonin	450 µg/L

The patient was discharged on his own free will and returned to Modena, Italy. There he performed additional investigations.

Whole-body scintigraphy and single photon emission computed tomography (SPECT) after intravenous injection of indium-111-octreotide showed hepatomegaly highlighting a large and high uptake halo that occupied almost the entire right hepatic lobe with other several liver focal accumulations. Also, a focal uptake localized in the small intestine, femoral neck, sternum and right shoulder were detected.

Liver biopsy was performed and the histology report showed a well differentiated neuroendocrine tumor with no necrosis or mitotic activity. Chemotherapy was initiated. Chemotherapy sessions were marked by severe granulocytopenia which needed growth factor correction and temporization of chemotherapeutic drugs.

A recent assessment (December 2013) showed clinical and biological improvement, with a stationary size of the hepatic lesions and decrease in size of the intestinal and bone tumors. In June 2014 liver ultrasound showed neoplastic hepatomegaly with multiple large nodular areas which increased in size compared to the previous examination, but with relative good clinical tolerance (fig. 3).

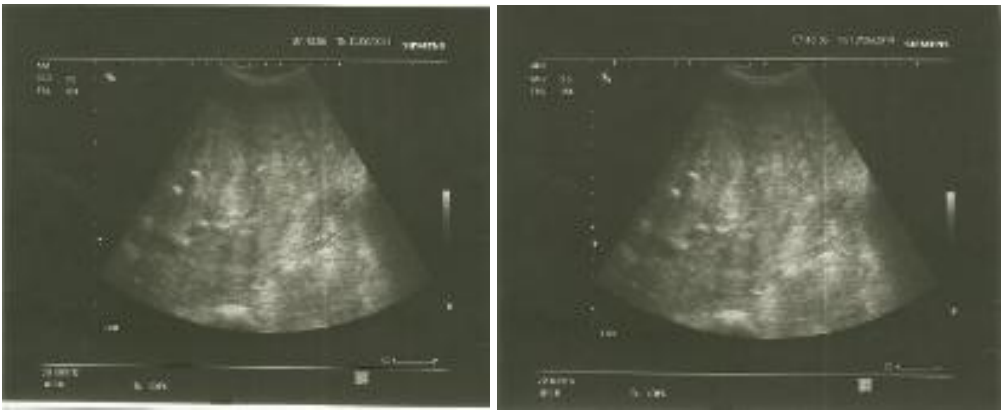

Fig. 3. Current liver ultrasound: multiple hepatic metastatic lesions

DISCUSSION

When liver metastasis occurs, the heart is exposed to intermittently high levels of vasoactive substances, which is believed to result in damage to the endocardium.

Carcinoid heart disease occurs in up to 60% of patients with carcinoid syndrome (8). Left-sided cardiac involvement can also occur in <10% of patients (2, 3, 10). The left side of the heart is relatively protected as the lungs filter the vasoactive peptides, inactivating them in the pulmonary circulation before they reach the left atrium (11). Therefore left sided disease is seen only in patients with bronchial carcinoid or patent *foramen ovale* or in those with poorly controlled severe carcinoid syndrome that overwhelms the degradation capacity of the lung (12, 13, 14).

Tumor size is an unreliable predictor of metastatic disease, and metastases have been reported even from tumors measuring less than 0.5 cm in diameter. Long-term survival correlates closely with the stage of

the disease at presentation (1). With regard to the clinical course of cardiac involvement, high urinary 5HIAA levels are a predictor of progression of carcinoid heart disease (10). This finding was corroborated by Bhattacharyya *et al* (11) who demonstrated that a urinary 5HIAA level greater than 300μmol/24 h and more than 3 flushing episodes per day are independent predictors of the development or progression of carcinoid heart disease.

The case presented is unique because the disease had a long and mostly mild progression, with the onset of left cardiac complications and liver metastasis prior to carcinoid syndrome manifestation. In our patient, carcinoid heart disease involved all 4 cardiac valves: the aortic valve to a higher extent than the pulmonary valve and the mitral valve to a worse extent than the tricuspid valve. It is hard to estimate if the severe left cardiac involvement is the soul result of carcinoid stress or the combined outcome of both degenerative and carcinoid disease.

CONCLUSIONS

The case presented had a peculiar development with silent liver metastases and left cardiac involvement, long disease progression and relatively favorable outcome. The primary goal of treatment in patients with NETs is curative, with symptom control and the limitation of tumor progression. However, as most patients with NETs are diagnosed once metastases have occurred, curative surgery is generally not possible. Octreotide decreases the secretion of serotonin by the tumor and can improve the symptoms of carcinoid syndrome and stabilize tumor growth in many patients. Unfortunately, there are no specific guidelines and no opportunity to accurately assess prognosis. Disease progression and overall survival are case dependent, as illustrated by the case here presented.

EVALUATION OF ADJUNCTIVE SYSTEMIC DOXYCYCLINE WITH NON-SURGICAL PERIODONTAL THERAPY WITHIN TYPE 2 DIABETIC PATIENTS

The aim of a study realized by a group of researchers from King Abdulaziz University, King Saud University, Riyadh, Kingdom of Saudi Arabia was to evaluate the effects of systemic doxycycline on clinical and microbiological parameters of diabetic subjects with chronic periodontitis. The 9-month multi-center, randomized, parallel, single-blinded study was conducted from different hospitals in Riyadh, Saudi Arabia between april 2010 - december 2010. A total of 76 diabetic subjects with chronic periodontitis were randomized into 2 groups: control group (CG) received only scaling and root planing (SRP), and the treatment group (TG) receiving systemic doxycycline during the reevaluation visit 45 days after the completion of SRP. Probing pocket depth, clinical attachment level, gingival index, plaque index, and bleeding on probing were collected at baseline, 45 days after SRP, and one, 3, and 6 months after the use of systemic doxycycline. Microbiological analysis comprised the detection of *Tannerella forsythia* (Tf), *Aggregatibacter actinomycetemcomitans* (Aa), *Porphyromonas gingivalis* (Pg), and *Prevotella intermedia* (Pi) by polymerase chain reaction method. Sixty-eight (33 CG and 35 TG) subjects completed the study. Greater reduction in the population of Tf, Pg, and Pi were observed in TG compared with CG in the first month after the administration of systemic doxycycline. The TG showed a significant improvement in gingival index scores compared with the CG by the end of the first and 6 months after the administration of doxycycline. The conclusion of the study was that the adjunct systemic doxycycline can be associated with a reduction of Tf, Pg, and Pi in the first month after the administration of doxycycline with an improvement in the GI. NUTRITIONAL FACTORS IN TRANSDIFFERENTIATION OF SCHELETAL MUSCLES INTO ADIPOCYTES (Abstract): A current area of interest is the determination of factors able to promote the transition from muscle to adipose tissue. The current review has highlighted that treatment of myoblasts with fatty acids (especially oleic acid) and thiazolidindiones causes conversion to adipocytes. The molecular mechanisms mediating the adipogenic action of thiazolidinediones and fatty acids in myoblasts could involve peroxisome proliferators-activated receptor-γ (PPARγ and CCAAT-enhancer-binding protein C/EBP . The role of 1,25-D_3 in adipogenesis is mediated at the molecular level through VDR-dependent inhibition of C/EBP and PPARγ expression and a decrease in PPARγ transactivation activity. Vitamin D supplementation increases muscle strength and ultimately reduces the incidence of falls. Additional research is needed to fully clarify the role of nutritional factors in adipogenesis. **Keywords**: TRANSDIFFERENTIATION, MYOGENESIS, ADIPOGENESIS, PEROXISOME PROLIFERATOR-ACTIVATED RECEPTORS, FATTY ACIDS, VITAMIN D.

Transdifferentiation is defined as the irreversible switch of one type of differentiated cell to another (1). Transdifferentiation is associated with a discrete change in the program of gene expression and there is a direct ancestor-descendant relationship between the two cell types. At molecular level, the cause of transdifferentiation is presumably a change in the expression of a master switch gene (selector or homeotic gene), whose normal function is to distinguish the two cell types in normal development (1).

TRANSDIFFERENTIATION OF SKELETAL MUSCLES TO ADIPOCYTES

Determination of the muscle and adipocyte lineages is controlled by a small number of tissue-specific transcription factors. In muscle, proteins MyoD and myf-5 play an important role in lineage determination, while the related factors myogenin and MRF4 function to execute the differentiation program (2). In adipocytes, differentiation appears to be controlled by two major factors or groups of factors: PPARs and the C/EBPs. However, a number of diverse lipids and lipid-like compounds can activate the PPARs, including fatty acids and synthetic arachidonate leukotrienes as well as drugs known to induce peroxisome proliferation.

Several pathologies of adult skeletal muscle are associated with increased in-

tramuscular adipose tissue. In the muscles of frail elderly people, muscle loss occurs and quality declines, with the accumulation of intramuscular fat and fibrosis impairing both contractile and metabolic function. Furthermore, there are also numerous diseases such as obesity and type 2 diabetes, as well as a range of muscular diseases where fibro-fatty accumulation occurs.

The essential role of satellite cells in muscle regeneration is well known, but it has been suggested that satellite cells, which are adult skeletal muscle stem cells can be diverted from the myogenic lineage and transformed into adipogenic cells under appropriate culture conditions *in vitro* and also *in vivo* (3).

Recently, a population of undifferentiated 'fibro-adipogenic' precursors (FAPs) isolated from mouse skeletal muscle was reported to differentiate into fibroblasts or adipocytes (4). Fatty acids (FAs) and adipocyte-inducing medium (AIM) treatment of human muscle fibroblasts induced a strong upregulation of PPARγ and C/EBP expression, and an extensive accumulation of lipid droplets (3). By contrast, when myogenic cells were exposed to AIM they failed to upregulate expression of either PPARγ or C/EBP , and did not accumulate lipid droplets. In another experiment, the human muscle-derived stem cells exposed to FAs and AIM accumulated some lipid, but showed no evidence of adipogenic differentiation (3).

BIOLOGIC IMPLICATION OF TRANSDIFFERENTIATION OF SCHELETAL MUSCLES TO ADIPOCYTES

The formation of muscle, bone, and adipose tissue are complex processes involving the determination of common precursor cells towards specific differentiation pathways. A current area of interest is the determination of factors that are able to promote the transition from one differentiated lineage to another, in particular, the transdifferentiation of muscle to adipose tissue. The imbalance between adipose and muscle mass is a hallmark of many disorders, including type 2 diabetes, obesity, and sarcopenia. Skeletal muscle and adipose tissue are key players in the development of insulin resistance, manifested by decreased insulin-stimulated glucose transport and metabolism in these tissues. It is known that myogenic cell lines and muscle satellite cells are capable of transdifferentiating to adipocytes, among other cell types (2). Thus, the study of transdifferentiation of muscle tissue to fat is highly applicable to the study of disorders where muscle atrophy and increase in adipose tissue mass are correlated.

Increased amounts of intramuscular adipose tissue are desirable in meat animals and are of interest to meat scientists. Raising lipid synthesis through feed is not economical (5). Therefore, assuming that myoblasts and adipoblasts have similar germinal origins (6), the possibility of transdifferentiation was hypothesized and tested to generate marbling or intramuscular adipogenesis.

PATHWAYS OF TRANSDIFFERENTATION OF MYOBLST TO ADIPOCYTE

The development of skeletal muscle is controlled by the muscle regulatory factors, such as myf-5, myogenin, and MyoD (7). Fusion of myocytes into multinucleated myotubes is the end step of muscle differentiation. In vitro, the major steps in muscle differentiation can be reproduced with myoblastic cell lines, such as C2C12 murine myoblast cells (8). Differentiation of

adipocytes appears to be controlled PPARγ and the C/EBP families of transcription factors (9). PPARγ, a nuclear hormone receptor, is expressed primarily in adipose tissue, and is induced early in the process of adipose differentiation. Fatty acids, natural and synthetic agonists of PPARγ, and vitamin D deficiency are known to promote adipogenesis (Fig. 1). These factors activate PPARγ resulting in the upregulation of adipocyte-specific genes, such as adipocyte lipid-binding protein 2 (aP2), Glut4, and fatty acid transporter. The mitogen-activated protein (MAP) kinase signaling pathways are crucial for the processes of myogenesis and adipogenesis (7).

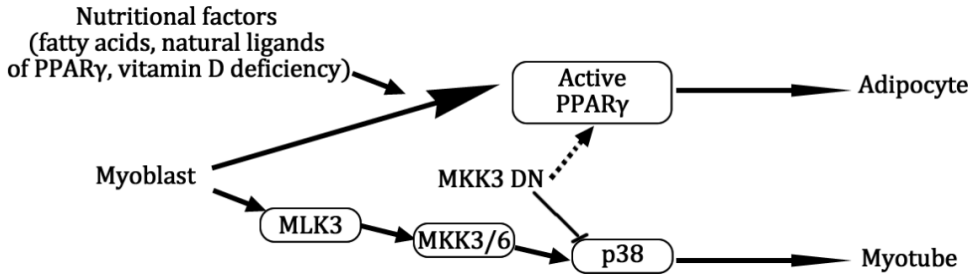

Fig. 1. This diagram summarizes the nutritional factors involved in transdifferentiation of myoblast to adipocyte [adapted from (7)]

Myoblasts and adipocytes arise from the same germ layer of the embryo, the mesoderm. Therefore, Li and collaborators hypothesized that it is possible to induce a direct conversion of myoblasts to adipocytes (6). Using a tissue model of myogenesis (G8 myoblasts), they demonstrated that these cells can differentiate spontaneously to myotubes when cultured in medium containing fetal calf serum. Subsequently, studies revealed that the expression of transcription factors such C/EBPα and PPARγ during the differentiation of G8 myoblasts can suppress the muscle- specific transcription factors (2). In addition, upregulation of PPARγ and subsequent activation of C/EBPα, β, and γ can stimulate adipogenesis in fibroblasts in the presence of PPARγ ligand (10). Thiazolidinediones (TZD), synthetic activators of PPARγ, are considered potent stimulators of adipogenesis and are presently used to reduce hyperglycemia in type 2 diabetes.

FACTORS IN TRANSDIFFERENTIATION OF SKELETAL MUSCLES TO ADIPOCYTES

Fatty acids. Inclusion of food rich in saturated fats or linoleic acid (LA) and n−6 polyunsaturated fatty acids (n−6 PUFAs) in the daily diet leads to insulin resistance (11). Many studies have also demonstrated that cis-unsaturated, nonesterified fatty acids, such as oleic acid (OA) and LA, exert a proliferative effect in cultured vascular smooth muscle (12, 13). OA induces proliferation of rat aortic smooth muscle cells by activating protein kinase C (13). These findings imply that fatty acids may play an important role in regulating skeletal muscle growth.

Hurley *et al.* have reported the pro-differentiation effects of fatty acids on

skeletal cell differentiation *in vitro* (14). On myoblast cell lines (rat cell line L6), the fatty acids showed different effects on muscle differentiation. The experiments indicated that inhibition of differentiation by the trans10, cis12 (t10, c12) isomer of conjugated LA (CLA) was dose-dependent (up to 200 mM) and may be via increased cell proliferation. LA and c9, t11 CLA stimulated differentiation at low concentrations (up to 50 mM), but inhibited differentiation at high concentrations (200 mM). In contrast, OA stimulated differentiation at all concentrations, whereas the saturated fatty acid, palmitic acid, had no effect. The mechanism appeared not to involve either PPAR or γ. The data suggest that only unsaturated fatty acids have an effect and the presence or absence of a cis-9 double bond may be important.

Natural agonist of PPARγ and thiazolidinediones. PPARs are members of the nuclear receptor superfamily that regulate the gene expression of proteins involved in energy, glucose and lipid metabolism, adipocyte proliferation and differentiation, and insulin sensitivity (15). PPARγ regulates fatty acid storage and glucose metabolism. The genes activated by PPARγ stimulate lipid uptake and adipogenesis by fat cells. The study of the natural agonist of PPARγ is in its infancy. The potential natural ligands of PPARγ are several unsaturated fatty acids, such as 15-hydroxiecosateraenoic acid, 9- and 13-hydroxy-octadecadienoic acid , 15-deoxy delta 12,14 prostaglandin J2, and PGJ2 (16).

Thiazolidinediones (TZDs) are an important class of synthetic agonists of PPARγ. TZDs are antidiabetic agents that target adipose tissue and improve insulin sensitivity, and they are currently used in the treatment of type 2 diabetes.

TZDs promote the transition from myogenic lineage to adipogenic lineage. The transition of porcine satellite cells from myogenic lineage to adipogenic lineage under the influence of ciglitizone or pioglitazone (TZDs), the adipogenic mixture, or both was observed (17). Similarly, the transition of C2C12 myoblasts to adipoblasts upon rosiglitazone (TZD) treatment (7) has also been reported. TZDs have been reported to have physio-logically relevant effects on semi-tendinosus muscle of postnatal pigs in potentiating marbling or intramuscular adipogenesis (18).

1,25 dihydroxy vitamin D_3. 1,25-Dihydroxyvitamin D (1,25-D_3), the active form of vitamin D, is widely recognized for its regulation of calcium and phosphate homeostasis in relation to bone development and maintenance and for its calcemic effects on target organs, such as intestine, kidney, and parathyroid glands. Emerging evidence has shown that vitamin D administration improves muscle performance and reduces falls in vitamin D-deficient older adults. However, little is known of the underlying mechanism or the role 1,25-D_3 plays in promoting myogenic differentiation at the cellular and/or molecular level.

Vitamin D, a fat-soluble secosteroid prohormone, is obtained from sun exposure or from dietary sources. 25-Hydroxivitamin D_3 is biologically inactive and is converted primarily in the kidney by the 25-hydroxyvitamin D-1-hydroxylase to its biologically active form 1,25-D_3 or calcitriol. Activation then enables 1,25-D_3 to bind to the vitamin D receptor (VDR), a type of nuclear receptor, and thereby regulates transcription of a number of vitamin D target genes, which is thought to be the

main mechanism of action of vitamin D.

VDR is expressed in human muscle tissue, which provides a rationale for a direct role of vitamin D in muscle function. Muscle biopsies in adults with severe vitamin D deficiency showed predominantly type II (fast-twitch) muscle, which may help explain the falling tendency of vitamin D-deficient elderly individuals (19). It has been reported that 1,25-D_3 induces genomic effects, leading to the synthesis of new proteins that affect muscle cell contractility, proliferation, and differentiation (20). Furthermore, mice lacking VDR show a skeletal muscle phenotype with smaller and variable muscle fibers and persistence of immature muscle gene expression during adult life, suggesting a role of vitamin D in muscle development (21).

Recent findings suggest that low (deficient) levels of 1,25-D_3 (i.e. 10^{-13} M) may actually enhance adipogenic trans differentiation (on murine C2C12 muscle cell line), whereas high (sufficient) levels (i.e. 10^{-9} M) inhibit adipogenesis, thereby potentially impacting on fat infiltration and muscle function (22). This increased accumulation of fat with low physiological concentrations (10^{-13} and 10^{-11} M) was associated with a sequential up-regulation of PPAR□2 (Pparg) and Fabp4 mRNA, indicating formation of adipocytes, whereas higher concentrations ($\geq 10^{-9}$ M) reduced all these effects. The nanomolar concentrations of 1,25-D_3 could inhibit adipogenesis and reduce the accumulation of triacylglycerol by 50% compared to fully differentiated control cells (23). In addition, treatment of preadipocytes with other vitamin metabolites, such as 24,25-dihydroxyvitamin D, could also inhibit preadipocyte differentiation, but at higher concentrations than 1,25-D_3 that paralleled their reduced affinity for the vitamin D receptor. This finding is consistent with the idea that any influence of vitamin D on adipogenesis would likely be exerted early in the preadipocyte to adipocyte transition when more VDR was available.

Recent studies, predominantly using the mouse 3T3-L 1preadipocyte cell culture model, have shown that the role of vitamin D in inhibiting adipogenesis is mediated at the molecular level through a VDR-dependent inhibition of C/EBP and PPARγ expression and a decrease in PPARγ transactivating activity in the preadipocyte (24). Also, in the presence of 1,25-D_3, VDR blocks adipogenesis by down-regulating both C/EBP mRNA expression and C/EBP nuclear protein levels at a critical stage of differentiation. In contrast, in the absence of 1,25-D_3, the unliganded VDR appears necessary for lipid accumulation, since knock-down of the VDR using siRNA both delays and prevents this process (25).

CONCLUSIONS

A current area of interest is the determination of factors that are able to promote the transition from muscle to adipose tissue. The change of skeletal muscle to adipocyte could be associated with certain diseases and may also be useful in the early diagnosis (e.g., diagnosis of insulin resistance), in the treatment of the disease itself (reversing the transformation of muscle to adipocyte in the development of sarcopenia), or in improving the meat quality by generating marbling or intramuscular adipogenesis in cattle and pigs. Nutritional factors, such as fatty acids or vitamin D deficiency, could modulate the expression of the genes involved in adipogenesis.

NEWS

CLINICAL EFFICACY OF POLYSPECIFIC INTRAVENOUS IMMUNOGLOBULIN THERAPY IN PATIENS WITH STREPTOCOCCAL TOXIC SHOCK SYNDROME

Streptococcal toxic shock syndrome (STSS) and necrotizing fasciitis are the 2 most severe invasive manifestations caused by group A *Streptococcus* (GAS). Intravenous immunoglobulin (IVIG) therapy has been suggested as adjunctive treatment with a beneficial effect on mortality. A study made by Linner et al aimed to document the clinical efficacy of administered IVIG therapy in a comparative observational study of well-defined patients with STSS. The study involved patients with STSS prospectively identified in a nationwide Swedish surveillance study conducted between April 2002 and December 2004. Detailed data on symptoms, severity of disease, treatment, and outcome were obtained from 67 patients. Twenty-three patients received IVIG therapy compared with 44 who did not. No significant difference in comorbidities, severity of disease, organ failures, or sex was seen, but the IVIG group was slightly younger and had a higher degree of necrotizing fasciitis (56% vs 14%). The primary endpoint was 28-day survival. Adjusted analysis revealed that factors influencing survival in STSS were Simplified Acute Physiology Score II (odds ratio [OR], 1.1; $P = .007$), clindamycin (OR, 8.6; $P = .007$), and IVIG (OR, 5.6; $P = .030$). This comparative observational study of prospectively identified STSS patients demonstrates that both IVIG and clindamycin therapy contribute to a significantly improved survival in STSS. (Linnér A, DarenbergJ, Jan SjölinJ, Normark BH et al.Clinical efficacy of polyspecific intravenous immunoglobulin therapy in patients with streptococcal toxic shock syndrome: A comparative observational study. *Clin Infect Dis*. (2014) 59 (6):851-857).

MALIGNANCY AND MORTALITY OF COLORECTAL POLYPS (Abstract) **Objectives**: To evaluate the rate of morbidity and mortality associated with colorectal polyps after the next 8-years period of endoscopic polypectomy, in a high risk managed care population. **Material and method:** Cohorts of 77 subjects with benign neoplasms were identified with a colonoscopy in 1999. Three groups of subjects: benign neoplasms with polypectomy, benign neoplasms without polypectomy, and no neoplasms were evaluated. Five years recurrence rates (1999-2004) of benign or new malignant colorectal neoplasms were identified: for the benign determined for the baseline benign neoplasms with polypectomy and no neoplasm groups neoplasm without polypectomy, only rates for malignancy were observed. Malignancy was evaluated with immunohistochemical p53 (tumor protein 53) and PCNA (Proliferating Cell Nuclear Antigen) staining pattern. Over the next 8 years 2004-2012 were evaluated the mortality and the recurrence rate of the benign polyps. **Results**: 77 subjects were enrolled in our study; 71.4% were diagnosed with benign and 2.5% with malignant neoplasms. The 5-years cumulative incidence rates of malignant colorectal neoplasms in the no neoplasm (n=20) and benign neoplasm groups (n=55) were (n=1) 5% and (n=10) 18.1%, respectively ($p < 0.005$). A lower 5-years malignancy rate was observed in benign neoplasms group with polypectomy (12%) compared to the benign neoplasm group without polypectomy (33.3%) ($p < 0.05$). The 8-years mortality rate was compared into benign recurrent polyps group and into malign group: the lower 8-years mortality rate was observed into benign polyp no neoplasm group (0%) and into benign recurrent polyps group (40%); the highest rate was observed into neoplasm group (100%). **Conclusions**: The high recurrence rate of benign colorectal neoplasms and a higher incidence of colorectal cancer in subjects at high risk-history of benign colorectal neoplasm-highlight a healthcare opportunity for surveillance and/or interventions to reduce the morbidity associated with colorectal neoplasms. **Keywords**: COLORECTAL POLYPS, POSTPOLYPECTOMY RECURRENCE, BENIGN POLYPS, PCNA, p53.

Over one million new cases of colorectal cancer (CRC) are diagnosed worldwide each year, and incidence seems set to rise with the progressive westernization of lifestyles in Asian and African populations.

Many colorectal cancers are thought to arise from adenomatous polyps in the co-

lon, defined as circumscribed lumps of epithelial dysplasia with uncontrolled crypt cell division. Single transformed cells may generate clones through new mutations, with the possibility of an enhanced growth rate. The present study was specifically designed to determine the recurrence rate of benign colorectal neoplasms in a managed care population over a 5-years period of follow-up. By using this defined population, the study also provided us the opportunity to estimate and compare the rate of development of malignant neoplasms in subjects' postpolypectomy and in subjects without polypectomy over 8 years following period postpolypectomy.

MATERIAL AND METHODS

77 subjects diagnosed with colonoscopy were categorized into three groups: benign neoplasms, malignant neoplasms, and no neoplasms. Subjects with a malignant neoplasm at baseline were excluded from the study. Thus, the remaining subjects had either benign neoplasms or no neoplasms detected based on the baseline colonoscopy. We further divided subjects with benign neoplasms at baseline into two groups: colonoscopy with polypectomy and colonoscopy without polypectomy (fig. 1). The subjects in the three diagnostic groups: no neoplasm, benign neoplasm with polypectomy, and benign neoplasm without polypectomy, were subsequently evaluated for up to 5 years. If at any time during the follow-up period a malignant neoplasm diagnosis was recorded, then that subject was excluded from subsequent follow-up. If at any time during the follow-up period a benign neoplasm was detected, then the subject was only evaluated further for estimating the rate of subsequent malignant neoplasm development.

For subjects who had no baseline neoplasms, we evaluated the subsequent incidence of benign and malignant neoplasms over the 5 years follow-up period. For subjects who had benign neoplasms at baseline and underwent polypectomy, we assessed the recurrence rates of benign neoplasms and the incidence of malignant neoplasms. For subjects who had benign neoplasms at baseline and did not undergo polypectomy, we evaluated the incidence of malignant neoplasms only; for this group the recurrence rate of benign neoplasms was not estimated. The 8 years malignancy rate was observed into benign recurrent neoplasm group *vs.* malign group. Malignancy was evaluated with immunohistochemical staining pattern of p53 and Proliferating Cell Nuclear Antigen (PCNA).

Chi-square analysis was conducted to check for differences in rates of benign and malignant colorectal neoplasms based on age and gender, malignancy in benign neoplasm subjects (with and without polypectomy) and, recurrence and incidence of benign neoplasms in subjects with benign neoplasm diagnosis and no neoplasm diagnosis at baseline, respectively. *EpiInfo* and *Statgraphics Plus 6.0* programs were used for statistical analyses; qualitative variables were compared by χ^2 test and Fischer's Exact Test (2-tailed, p-level < 0.05).

RESULTS

The percentage of subjects with benign and malignant neoplasms at baseline were 71.4 (n=55) and 2.5 (n=2), respectively. Males appeared to have a higher rate of benign (46% *vs.* 33%) ($p<0.001$) and malignant neoplasms (5.7% *vs.* 5.2%) ($p > 0.05$) than females. In general and as expected (7, 8) the rate of benign or malignant neoplasms increased with increasing

age ($p < 0.001$). Subjects without neoplasms (n=20) and benign neoplasms (n=55) at baseline colonoscopy were included in subsequent analyses.

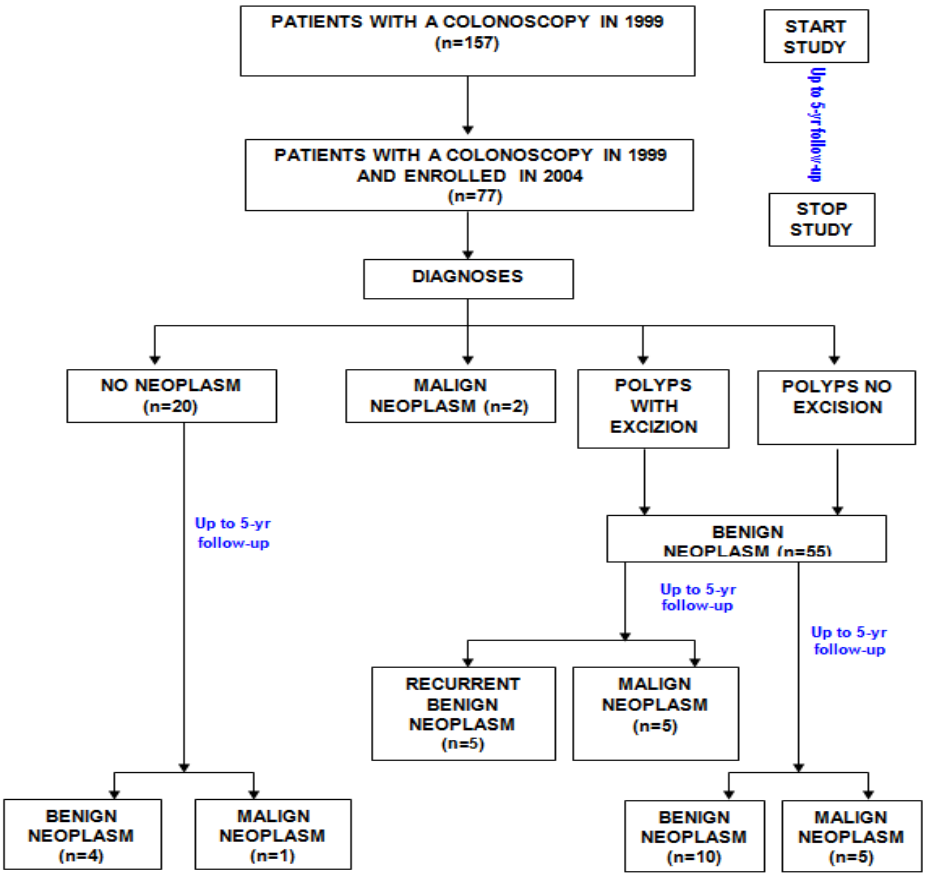

Fig. 1. Follow-up of Subject Cohort

Five-year diagnostic outcomes of these subjects are presented in table I. Among 20 subjects without neoplasm at baseline, the incidence rate of benign neoplasms ranged from 0 to 10 % for each year with a 5-year cumulative rate of 20%. In the same cohort, the incidence rate of malignant neoplasm ranged from 0 to 5 % for each year with a cumulative rate of 5%. It is interesting to note that of the 55 subjects with benign neoplasms at baseline (with and without baseline polypectomy), 10 subjects (18.1%) develop malignant neoplasms over the subsequent five years, which was significantly higher ($p<0.05$) than the rate observed in the subjects without neoplasms at baseline (5%). The highest rates of malign neoplasm follow-up from no neoplasm at baseline were observed during the 4th year of study (5%); in the 4th year of study was observed the maximum of benign neoplasm at follow-up from no neoplasm at baseline

(10%). The adenomatous polypoidal character and carcinomatous polypoidal character were established by immunohisto chemical staining for p53 and PCNA.

TABLE I

Five-year diagnostic outcomes of patients with no neoplasms baseline

Diagnosis at Colonoscopy	Years										Cumulative rate	
	1st		2nd		3rd		4th		5th			
	No	%	No	%	No	%	No	%	No	%	No	%
No neoplasm at baseline	20	100	20	100	19	95	17	85	16	80	20	100
Benign neoplasm at follow-up FROM No neoplasm at baseline	0	0	0	0	1	5	2	10	1	5	4	20
Malign neoplasm at follow-up FROM No neoplasm at baseline	0	0	0	0	0	0	1	5	0	0	1	5

Table II presents results for subjects entering the study with a baseline benign neoplasm (n=55 patients). For those subjects who had a baseline polypectomy (40 patients) the rates of recurrent benign neoplasms and the incidence of malignant neoplasms are reported. For subjects without baseline polypectomy (15 patients) only the rate of malignant neoplasms is reported. As can be seen, the yearly rates of benign neoplasm recurrence for the post-polypectomy group ranged widely from 5% to 12.5%; the highest rates were observed during the last two years. To assess the effect of polypectomy on the rate of subsequent malignancies, the rates of malignant neoplasms at follow-up were compared for the two groups: with and without polypectomy. As expected polypectomy was associated with a lower five year cumulative rate (20%) as compared to no polypectomy (73.3%) ($p < 0.05$). The 5-years cumulative incidence rates of malignant colorectal neoplasms in the no neoplasm (n=20) and benign neoplasm groups (n=55) were (n=1) 5% and (n=10) 18%, respectively ($p < 0.005$). A lower 5-years malignancy rate was observed in benign neoplasms group with polypectomy (12%) compared to the benign neoplasm group without polypectomy (33.3%) ($p < 0.05$).

In patients without polypectomy, the malignancy was evaluated by immunohistochemical staining pattern of p53 and PCNA; to patients with initial polypectomy (1999) immunohistochemical pattern of p53 and PCNA confirmed the malign neoplastic lesions.

Comparing the five year cumulative incidence of benign neoplasms in subjects without a baseline neoplasm (n=4; tab. I) to those with a baseline benign neoplasm with

polypectomy (n=15; tab. II) it is obvious that the 5-years cumulative recurrence rate of 40% was significantly greater ($p < 0.005$) than the 5% rate in subjects without baseline neoplasm. These data demonstrate the risk associated with a past history of benign tumors (high risk).

The 8 years (2004-2012) mortality rate was compared into benign recurrent polyps group, into benign group and into malign group: the lower 8-years mortality rate was observed into benign polyp no neoplasm group (0%) and into benign recurrent polyps group (40%); as expected the highest rate was observed into neoplasm group (100%) ($p < 0.005$) (fig. 2).

TABLE II

Five-year diagnostic outcomes of patients undergoing colonoscopy and with the diagnosis of benign neoplasms at baseline (with *v*. without polypectomy)

Benign Neoplasm at Baseline	Years									
	1st		2nd		3rd		4th		5th	
	No.	%	No.	%	No.	%	No.	%	No.	%
Colonoscopy with polypectomy	40	100	40	100	40	100	40	100	40	100
→ Recurrent benign neoplasm:	0	0	2	5	4	10	5	12.5	5	12.5
Colonoscopy with polypectomy	40	100	40	100	40	100	40	100	40	100
→ Malign neoplasm:	0	0	0	0	2	5	1	2.5	5	12.5
Colonoscopy without polypectomy	15	100	15	100	15	100	15	100	15	100
→ Malign neoplasm:	0	0	0	0	3	20	3	20.0	5	33.3

DISCUSSION AND CONCLUSIONS

In present, there are reported several studies with estimated rate of benign polyp recurrence with widely varying results. So, National Polyp Study (9), a prospective clinical trial, the reported cumulative rate of adenomatous polyp recurrence was 41.7% when subjects were examined with colonoscopy at one and three years and 32% when examined at only three years. Our results indicate a similar polyp recurrence rate (40%) (tab. II) over a 5 years' time frame; the estimate of the three-year polyp recurrence rate (15%) in our study was Whereas our results are numerically similar, it must be noted that the study populations and conditions for follow-up varied greatly between our study and the National Polyp Study. In National Polyp Study were included the subjects with adenomatous polyps only. Additionally, the National Polyp Study was a prospective trial with scheduled colonoscopies. In contrast, no such procedures were required in our analysis. Despite these very significant differences, our naturalistic retrospective study still was numerically similar in its findings. Our study did not explore the reasons for performing colonoscopy. Different reasons for colonoscopy (for "cause" *vs.* surveillance *vs.* screening) could influence and lead to different rates of colorectal neoplasm detection. In light of this limitation, the conclusions of this study are

limited to recurrence rates in subjects with a baseline neoplasm, without consideration to the clinical indication associated with the baseline colonoscopy.

To assess the effect of polypectomy on the rate of subsequent malignancies, the rates of malignant neoplasms at follow-up were compared for the two groups: with and without polypectomy. In our study (tab. II), as expected, polypectomy was associated with a lower five year cumulative rate (20%) as compared to no polypectomy (73.3%) ($p < 0.05$). Most of colorectal cancers that occur within 5 years after colonoscopic polypectomy develop because of failure to identify or completely remove high-risk neoplasms (advanced adenomas or cancers) at the time of the initial colonoscopy (10, 11). The adequacy of a polypectomy is assessed according to the endoscopic appearance of the polypectomy site and by a review of the pathological specimen to determine whether its margins are free of neoplastic tissue. The adenoma "miss rate" which can vary by a factor of 2 to 3 among examiners, is about 6 to 12% for adenomas that are 1 cm or larger and up to 25% for smaller adenomas (12, 13, 14). Thus, missed adenomas or cancers may contribute to the occurrence of colorectal cancer despite colonoscopic surveillance and may underlie many instances of "metachronous" neoplasia reported during surveillance. To be most effective, colonoscopy should be performed by well-trained, certified endoscopists who meticulously examine the entire colon during withdrawal of the instrument.

There is a higher rate of recurrence of benign and malignant neoplasm detected in our study population in the last two years. This may reflect early recurrence of symptoms, repeated examinations and the detection of neoplasms that may have been missed on the baseline evaluation. Additionally, and despite national guidelines to the contrary, these examinations may have been scheduled early for subjects thought to be at high risk. With increased surveillance a higher rate of recurrences may have been estimated in these shorter time frames.

Our study (fig. 2) indicated a higher rate of lesional prevalence to men of benign (46% *vs.* 33%) ($p < 0.001$) and malignant neoplasms (5.7% *vs.* 5.2%) ($p > 0.05$) than females. In general and as expected (7, 8) the rate of benign or malignant neoplasms increased with increasing age ($p < 0.001$). Similar results were reported from Jemal, Siegel and Ward that appreciated colonic adenomas, the precursors of almost all sporadic colorectal cancers, are found in up to 40% of persons by 60 years of age (1).

Although controlled trials have not compared surveillance intervals that are longer than 3 to 4 years, the low rate of colorectal cancer after 5 to 6 years of follow-up in patients with only one or two small, tubular adenomas on initial colonoscopy (15, 16, and 17) suggests that a follow-up interval of 5 or more years is safe for these patients.

The adenoma–carcinoma sequence the progression from normal colonic mucosa to small tubular adenomas to larger adenomas and those with more advanced histological features (villous features, high-grade dysplasia, or both) to cancer is a central tenet of our understanding and management of colonic adenomas. Although not all colonic polyps are adenomas (hyperplasic polyps account for about half of small, rectosigmoidian polyps) and more than 90% of adenomas do not progress to cancer, it is currently not possible to reliably identify those that will progress. Thus, colonic polyps identified at colonoscopy should be

removed if it is technically feasible to do so.

Complete removal of a colonic adenoma eliminates the risk of cancer from that adenoma, but the finding of a colonic adenoma may indicate an increased risk of metachronous adenomas and colorectal cancer for both the patient and his or her first-degree relatives (i.e., parents, siblings, and children). Colonic adenomas are typically asymptomatic and are most commonly found by means of colonoscopic or radiological imaging studies performed because of unrelated symptoms or for colorectal cancer screening. Since at least 25% of men and 15% of women who undergo colonoscopic screening by experienced endoscopists are found to have one or more adenomas, the cumulative burden of subsequent surveillance colonoscopy on the health care system is substantial.

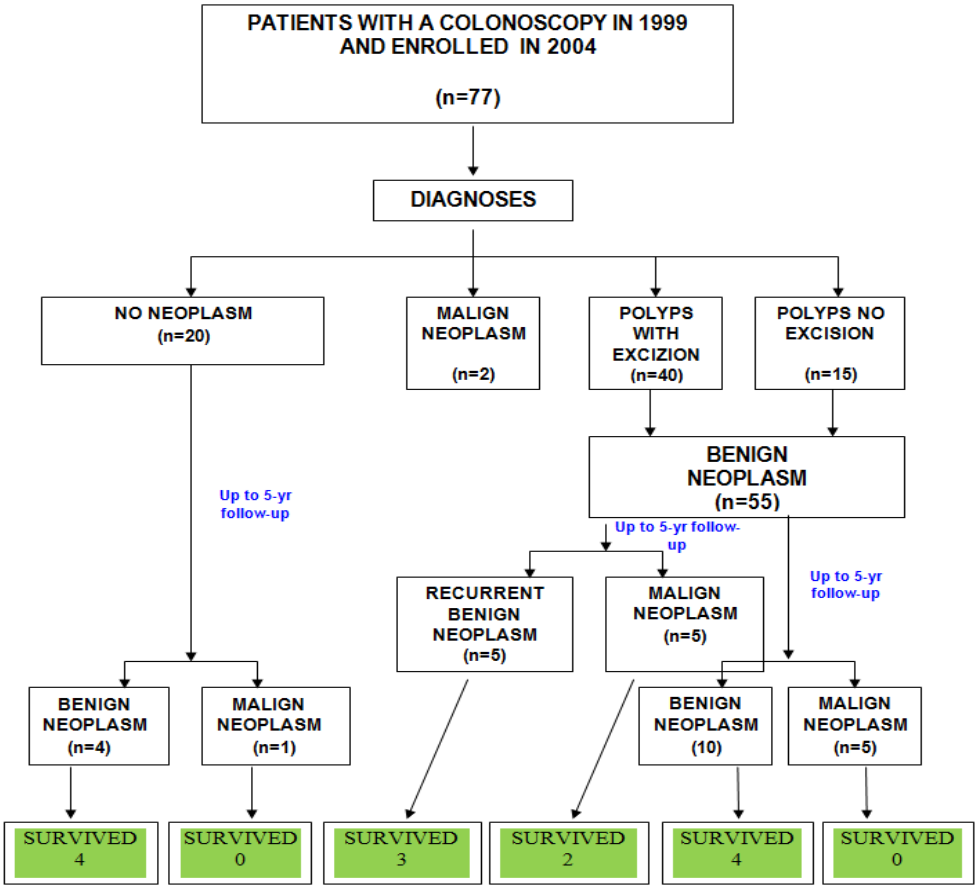

Fig. 2. 8-Year Follow-up of Subject Cohort

The high recurrence rate of benign colorectal neoplasms and a higher incidence of colorectal cancer in subjects at high risk-history of benign colorectal neoplasm-highlight a healthcare opportunity for surveillance and/ or interventions to reduce the morbidity associated with colorectal neoplasms. The active interventions for health

care providers can include adherence to colonoscopic guidelines for surveillance in high-risk populations and possibility the use of secondary chemoprevention to prevent the morbidity and mortality associated with colorectal neoplasms.

THE EFFECTS OF TWO POLYMERIC MATRICES FOR INDOMETHACIN IN CUTANEOUS NOCICEPTIVE REACTIVITY IN MICE (Abstract): **Aim**. This paper is focused on the investigation the effects of two polymeric matrices for indomethacin in cutaneous pain models in mice. There were used two different co-polymers polyhydroxyethyl methacrylate and undecan, polymerization reactions being conducted under nitrogen, at 80^0C. **Material and methods:** The experiments were carried out on white Swiss mice (20-25 g), divided into 6 groups of 7 animals each, treated orally. Biocompatibility properties of indomethacin-loaded co-polymeric matrices ware evaluated by assessing the effects on the blood parameters, the serum biochemical tests of animals treated. The nociceptive somatic testing was performed using hot plate assay and tail immersion test. The latency (second) response to paw, respectively tail thermal noxious stimulation, was measured before the experiment and 15, 30, 60, 90, 120 minutes, 4, 6, 8, 10, 12 hours after the substances administration. **Results:** Laboratory analysis did not show significant differences of blood parameters, serum biochemical tests between control mice group (IND) and groups treated with 1 M, 1 IND, 3 M, 3 IND. In our experimental conditions IND determined a significant increasing of the latency period response, in hot plate and also in tail immersion tests. Using two different co-polymers for indomethacin incorporation we obtained an increasing of the latency time pain reaction in hot plate assay, respectively in tail immersion test, statistically significant (*$p< 0.05$) compared with the simple co-polymers administration. **Conclusions:** We demonstrated that indomethacin co-polymeric matrices 1 IND and 3 IND determined similar immune responses with indomethacin and simple co-polymers after oral administration in mice, indicative of good *in vivo* biocompatibility. Oral administration of both 1 IND and 3 IND resulted in prolonged antinociceptive effects in hot plate assay and also in tail immersion test in mice. **Keywords:** INDOMETHACIN, POLYMERIC MATRICES, HOT PLATE, TAIL IMMERSION.

According to its colossal potential in medicine and medical technologies, the actual directions of nanomedicine are represented by the development of the basic sci-

ences experiments according to the multidisciplinary vision of the nanoscience, and training programs particularly for young researchers in this field. The importance of nanomedicine is represented by the opportunity of understanding the molecular and genetic level of pathophysiological mechanisms of the diseases, the improvement of pharmacotherapeutic management due to targeted action of drug loaded nanoparticulate systems, and reducing the side effects of substances. Nowadays the use of nanoparticulate formulations is under research in experimental studies and in clinical trials (1, 2). Nanoparticle drug carriers consists of solid biodegradable particles in size ranging from 10 to 1000 nm in which the substances is dissolved, entrapped or encapsulated, and/or to which the active principle is absorbed or attached (3). The development of analgesic drugs loaded nanoparticulate systems may represent a future challenge to realize promising agents for local drug delivery in inflammatory and painful conditions (4, 5).

The supposition that the utilization of various materials at the nanometer scale, will determine the improvement of different pharmaco-dynamic actions of active substances entrapped in them is based on different experimental reports indicating the possibility of reaching otherwise less accessible sites in the body and also the sustained release of various drugs (3, 4).

To directly prove this hypothesis we investigated the effects of two polymeric matrices for indomethacin in hot plate and tail immersion tests. The performed studies are significant because they offer a fundamental perspective on the self-assemblage processes from the bio-molecular systems and also represent a basis for controlled release applications which can be valuable for the biomedical and pharmaceutical fields.

We aimed to investigate the effect of two polymeric matrices for indomethacin in two different experimental cutaneous pain models in mice.

MATERIAL AND METHODS

Materials: 2 - Hydroxyethyl Methacrylate (HEMA) (from Fluka, purity>96%) was purified by passing it through an inhibitor removal column. The inhibitor - remover replacement packing (for removing hydroquinone (HQ) and hydroquinone monomethyl ether (MEHQ) was purchased from Aldrich. 3,9-divinyl-2,4,8,10-tetraoxaspiro[5.5]undecane (U) (Aldrich, 98%), sodium lauryl sulfate ($C_{12}H_{25}O_4SNa$) – (SLS) from Sigma (c > 95 wt %), PAV (polyvinyl alcohol) and the radical initiator 4,4'-azobis(cyanopentanoic acid) (ACPA) (Fluka, 98%), were used without further purification. In all experiments it was used twice distilled water which contained no foreign ions. The water used in all experiments was purified using an Ultra Clear TWF UV System.

Male white Swiss mice (20-25g) were used. Lighting was on a 12-h light/dark cycle (lights on at 6:00 a.m.), with standard laboratory food and tap water freely available, except during the time of the experiments. Before the experiment, mice were placed on a raised wire mesh, under a clear plastic box and allowed 2 hours to acclimate to the testing room.

Methods: The drug powder (about 10 wt% of the copolymers weight) was dissolved in ethanol/phosphate buffer solution (pH=7.2) 50:50. The obtained drug concentration in the initial loading solution was $c=1.9005\times10^{-5}$ mol/ml. The co-polymers (approximately of the same weight) were immersed in this solution and swollen to

equilibrium. Polymerization reactions were conducted under nitrogen atmosphere (nitrogen purged to remove oxygen), at 80^0C in a constant temperature bath, with a mechanical stirring rate of 180 rpm (6). The swollen drug-loaded samples were then dried at ambient temperature for several days to constant mass and used for the release experiments. After synthesis the polymeric particles were precipitated three times with methanol from water solution and finally freeze-dried by lyophilization during 24 hours (7).

The experiments were carried out on white Swiss mice (20-25 g), divided into 6 groups of 7 animals each, treated orally (using an eso-gastric device) as follows groups: I (Control): 0,1ml/10g weight; II (IND): indomethacin 5mg/kbw (IND); III (1 M): polyhydroxyethyl methacrylate (HEMA) 10% + polyvinyl alcohol (APV); IV (1 IND): HEMA 10% + APV + IND 5mg/kbw; V (3 M): HEMA 10% + undecan 3,5% + APV; VI (3 IND): HEMA 10% + undecan 3,5% + APV + IND 5mg/kbw. The experiment was performed according to the "Grigore T. Popa" University of Medicine and Pharmacy guidelines, for handling of experimental animals, also to the recommendations and policies of the International Association for the Study of Pain. Each animal was used once only and sacrificed immediately after the experiment (8).

RESULTS AND DISCUSSION

Biocompatibility evaluation. We evaluate the acute toxicity of indomethacin-loaded co-polymeric matrices, by assessing the effects on the blood count, the serum biochemical tests (glutamic oxaloacetic transaminase (GOT), glutamic pyruvic transaminase (GPT) and lactic dehydrogenase (LDH) activity) and on some immune system parameters (serum opsonic capacity (OC), phagocytic capacity (PC) and bactericidal capacity (BC) of peritoneal macrophages). Data were expressed as mean ± S.E.M. and statistically analyzed using t-student of Windows EXCEL program test.

Hot plate test. The nociceptive somatic testing was performed using hot plate assay to determine the latency of nocifensive reactions evoked by thermal heat stimuli applied on the paws. In this test, animals were individually placed on a hot plate maintained at a constant temperature ($55+0.3^o$C). The latency to first sign of hind paw licking or jump response to avoid heat nociception was taken as an index of nociceptive threshold (9). Pre-dosing latencies (seconds) were measured before administration of any drug or vehicle. The baseline latency (before drug injection) in hot plate test was 4.2±0.2 seconds (mean ± standard error of mean - SEM) (10). The recommended cut-off time of 12 seconds was used to prevent tissue damage. Latency time response is measured at 15, 30, 60, 90, 120 minutes, 4, 6, 8 hours after the substances administration. Differences between the experimental and baseline latencies are interpreted as an index of analgesia. Increases in the latency time response for the mouse to avoid thermal stimulus are indicative of analgesia, while decreases in the latency reaction are indicative of hyperalgesia (11). Response latency data from paw reaction latency were converted to per cent of maximum possible effect (%MPE) according to the formula: %MPE = [(observed latency-baseline latency)/(cut off time–baseline latency)] × 100 (12).

Tail immersion test. The effects of these two polymeric matrices for indomethacin were assessed in tail immersion test. The apparatus consists of a water bath heated to

a nociceptive temperature of approximately 54°C. The animal is placed into individual restraining devices leaving the tail hanging out freely. The lower 5 cm segment of the tail is immersed in the bath hanging out freely. The lower 5 cm segment of the tail is marked. This part of the tail is immersed in the water bath. Within a few seconds the animal reacts by flicking its tail and the latency to withdrawal the tail as a response to noxious thermal stimulation is measured by stop watch (9, 12). The baseline latency (before drug injection) in the tail immersion test was 5.5 ± 0.3 seconds (mean ± standard error of mean - SEM). The recommended cut-off time of 15 seconds was used to prevent tissue damage. Differences between the experimental and baseline latencies are considered as an index of analgesia. Prolongation of the reaction time to the typical tail-withdrawal reflex is an indicative of analgesia, while reduction in tail-flick latency corresponds to a hyperalgesic effect. The tail-withdrawal reactivity (seconds) was recorded before administration of any drug or vehicle. Latency time response was determined 15, 30, 60, 90, 120 minutes, 4, 6, 8, 10, 12 hours after substances administration. Response latency data from tail withdrawal measurements were converted to per cent of maximum possible effect (%MPE) according to the formula: % MPE = [(observed latency-baseline latency) / (cut off time – baseline latency)] × 100 (11).

In both experiments, results of time response from each group were calculated as mean ± standard error of mean (SEM) and significance was tested by *SPSS 13.0* Statistics and ANOVA method, followed by Neumann Keuls test as *post hoc*. *p*-values less than 0.05 are considered statistically significant comparing with those of control group. Laboratory analysis did not show significant differences of leucocyte formula elements, GOT, GPT and LDH levels, nor immune parameters (OC, PC, BC), between control mice group (IND) and groups treated with 1 M, 1 IND, 3 M, 3 IND relevant elements for a good *in vivo* biocompatibility. The behavioral reflex evoked by noxious heat stimuli is a relatively good predictor of pain sensitivity and for the study of the antinociceptive actions of different substances.

In our experimental condition in models of hot plate and tail-immersion in mice, which are measures of thermally-induced pain, the two polymeric matrices for indomethacin increased nociceptive pain threshold, actions that are prolonged comparing with the effects of simple drug administration. Statistical analysis of the results obtained in hot plate test shows that indomethacin (IND) determined a rapidly and statistically significant ($p<0.05$) increasing of the latency time period of the response, effect prolonged 4 hours after oral administration of the substance. Then the effect of indomethacin was gradually decreased ($p<0.05$) to 8 hours after its administration. The results of our experimental study are congruent with the literature communicated data, regarding the effects of the nonsteroidal antiinflammatory drug indomethacin, in this experimental cutaneous pain model in mice (13). The administration of co-polymers 1 M and 3 M did not influence the latency time response to thermal noxious stimulus in this cutaneous pain model. Using two different copolymers for indomethacin incorporation we obtained an increasing of the latency time pain reaction in hot plate test, statistically significant compared with simple copolymers (*$p< 0.05$) (fig. 1).

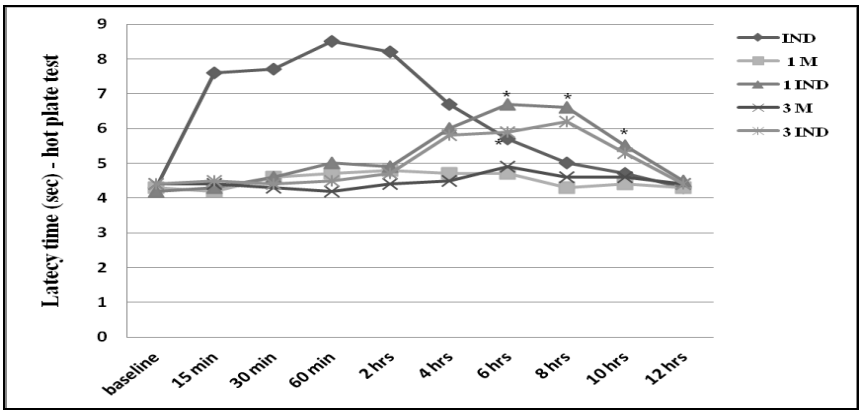

Fig 1. The latency time of IND, 1 M, 1 IND, 3 M, 3 IND response to thermal noxious paw stimulation, in hot plate test. Each point is the mean ± SEM of latency time (seconds) for seven mice. *p<0.05, **p<0.01 *vs.* control. Both 1 IND (6.7±0.1 after 6 hours, 6.6±0.7 after 8 hours, 5.5±0.3 after 10 hours) and 3 IND (5.9±0.7 after 6 hours, 6.2±0.9 after 8 hours, 5.3±0.5 after 10 hours) increases the latency time period, statistically (*p<0.05) significant *vs.* control.

Both 1 IND and 3 IND proved the retard release of the non-steroidal anti-inflammatory indomethacin from the synthesized polymer networks, 1 IND eliciting a higher effect than 3 IND in the somatic pain model used.

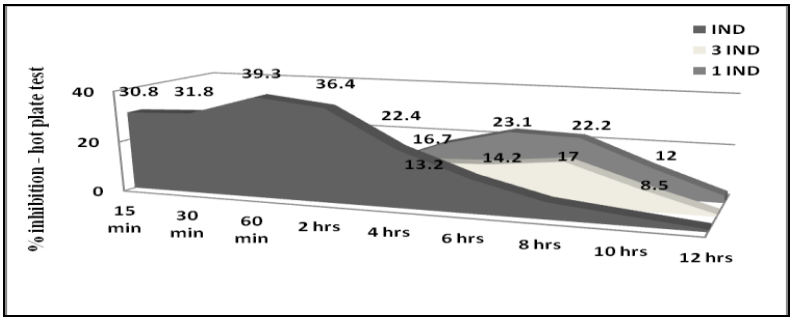

Fig. 2. Time course of the maximum possible effect (%MPE) of IND, 1 M, 1 IND, 3 M, 3 IND on the paw latency response in hot plate test. Each point is the mean ± SEM of percentage of maximum possible effect (%MPE) for seven mice.

Moreover, we used the percentage of maximum possible effect (%MPE), to quantified the intensity of antinociception which is important to corroborate and confirm these previous results. Indomethacin administration resulted in an increase in %MPE in hot plate assay, statistically significant in a first 2 hours after substance administration. The higher percent of inhibition was obtained in the interval between 60 minutes (39.3%±1.7) and 90 minutes (36.4%±2.3) in the experiment. Oral administration of 1 IND determined an increase of response latency in the hot plate

test, after 2 hours, effects prolonged around 8 hours, with a higher values in the interval between 6 hours (23.1%±1.3) and 8 hours (22.2%±2.5), after substance administration. 3 IND produced a significant increase of response latencies between 4 hours (12.2%±2.1) and 8 hours (17%±0.9) after substance administration, but less than submaximal level in the hot plate test (< 60% of MPE) (fig. 2).

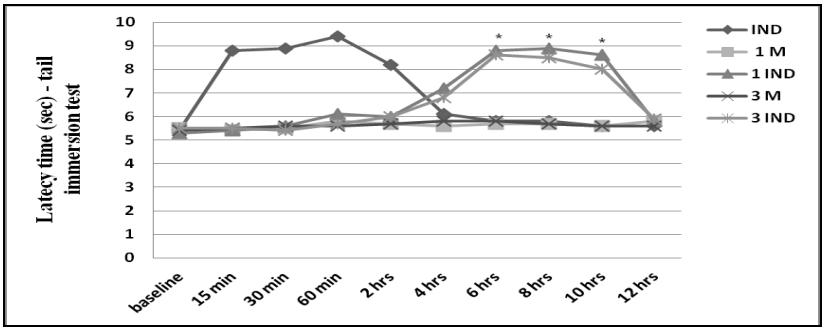

Fig 3. The latency time of IND, 1 M, 1 IND, 3 M, 3 IND response to thermal noxious tail stimulation, in tail immersion test. Each point is the mean ± SEM of latency time (seconds) for seven mice. *p<0.05, **p<0.01 vs control. Both 1 IND (7.2±0.7 after 4 hours, 8.8±0.3 after 6 hours, 8.9±0.5 after 8 hours, 8.6±0.9 after 10 hours) and 3 IND (6.8±0.3 after 4 hours, 8.6±0.5 after 6 hours, 8.5±0.1 after 8 hours, 8.0±0.7 after 10 hours) increases the latency time period, statistically (*p<0.05) significant vs control.

Indomethacin oral administration produced a rapidly and statistically significant (p<0.05) increasing of the latency time period of the response, effect prolonged 2 hours in the experiment. After this time its effect was gradually decreased (p<0.05) to 6 hours after its administration. These results are in concordance with data existing in literature, regarding the effects of indomethacin, in this experimental somatic pain model in mice (14). The treatment with 1 M and 3 M co-polymers did not influence the latency time response to thermal noxious stimulus in tail immersion test. The administration of co-polymers including indomethacin resulted in an increasing of the latency time response, statistically significant (*p< 0.05) compared with simple co-polymers (fig. 3).

Both 1 IND and 3 IND used demonstrated the prolonged release of the indomethacin from the polymer matrices. The effect of 1 IND was most intense than the effect of 3 IND in tail immersion model.

In these two experimental pain models used the retard release of the drug from the polymer network may be explicated as it follows: 2 - Hydroxyethyl Methacrylate is coupling indomethacin by hydrogen bonds through hydroxyl groups and release the active substance after bursting the physical links. The association of 3,9-divinyl-2,4,8,10-tetraoxaspiro[5.5]undecane facilitated the formation of both intra and intermolecular physical bonds and at the same time induced steric hindrances generated by the spiroacetal groups. Much more it functioned as cages which coupled and retained of the drug into the network meshes, slowing down of the bioactive substance release from them (15).

The treatment with indomethacin de-

termined an increase in %MPE statistically significant in a first 2 hours after substance administration, in tail immersion test. The higher percents of inhibition were obtained in the interval between 30 minutes (36.5%±0.9) and 60 minutes (41.7%±1.3) after substance administration. 1 IND administration resulted in a significant increase in inhibition percent between 6 hours (36.1%±1.2) and 10 hours (34%±0.7), but with a peak value 8 hours (37.1%±1.3) in the experiment. 3 IND produced an increase in inhibition percent after 2 hours, effects prolonged around 10 hours, with a higher values in the interval between 6 hours (32.6%±0.7) and 8 hours (31.6%±1.1), after substance administration (fig. 4).

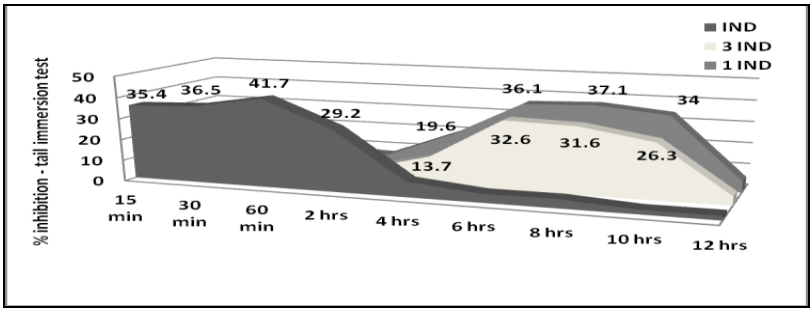

Fig. 4. Time course of the maximum possible effect (%MPE) of IND, 1 M, 1 IND, 3 M, 3 IND on the tail withdrawal response in tail immersion test. Each point is the mean ± SEM of percentage of maximum possible effect (%MPE) for seven mice.

CONCLUSIONS

We evaluated the *in vivo* biocompatibility and investigated the effects of different copolymeric metworks based on 2- Hydroxyethyl Methacrylate in association with 3,9-divinyl-2,4,8,10-tetraoxaspiro[5.5] undecane, using polyvinyl alcohol as protective colloid for indomethacin incorporation in somatic nociceptive reactivity in mice.

Indomethacin co-polymeric matrices 1 IND and 3 IND determined similar immune responses with indomethacin and co-polymers after oral administration in mice, indicative of good *in vivo* biocompatibility. The administration of both indomethacin co-polymeric matrices 1 IND and 3 IND proved antinociceptive effects in hot plate test in mice. Oral administration of these two co-polymeric networks including indomethacin 1 IND and 3 IND resulted in a significant and prolonged analgesic effect in tail immersion test.

The good *in vivo* biocompatibility and the antinociceptive evident effects of different copolymeric systems including indomethacin attests the possibility for using these compounds as innovative drug-carriers with applicability in biological and medical fields.

NEW APPROACHES AGAINST ANTIFUNGAL DRUG RESISTANCE

Fluconazole (FLC) is widely used in the treatment of candidiasis because of its efficacy and low toxicity. The emergence of FLC-resistant *Candida albicans* isolates and biofilm-associated infections pose a great challenge to antifungal treatment. According to Liu *et al.*, in order to increase the susceptibility of *C. albicans* to FLC different combinations of FLC with non-antifungal agents have been proposed, such as: calcineurin inhibitors, antibacterials, calcium homeostasis regulators, heat shock protein 90 inhibitors and traditional Chinese medicine drugs. The modes of action of these compounds and the mechanisms of their synergistic effects against resistant strains of *C. albicans* are: increased membrane permeability, reduced efflux of antifungal drugs, interference with intracellular ion homeostasis, inhibition of enzymes required for fungal survival, and inhibition of biofilm formation. The study concludes that the reversal of fungal resistance can be achieved through various mechanisms (Liu S1, Hou Y2, Chen X3.et al. Combination of fluconazole with non-antifungal agents: A promising approach to cope with resistant Candida albicans infections and insight into new antifungal agent discovery. *Int J Antimicrob Agents*. 2014 pii: S0924-8579(14)00002-8. doi: 10.1016/j.ijantimicag.)

THE BODY MASS INDEX IN RELATION WITH THE SELF-PERCEPTION OF WEIGHT AND THE BODY COMPOSITION FROM DIFFERENT POPULATIONAL GROUPS (Abstract): The purpose of this paper is to analyze the self-perception of weight in relation with the body mass index and the body composition of three working groups composed of physically untrained young students, young athletes and patients diagnosed with chronic diseases. The working groups consisted of 110 participants: untrained students, athletes and dialysed patients; 50.9% women and 49.1% men; with an average age of 26.03. The BMI of the patients is significantly higher than the BMI of the athletes and untrained students. No significant differences were found between groups in terms of self-perception of weight. Compared to the physically untrained students and patients, the athletes have a significantly higher level of muscle tissue. The athletes also have a significantly lower adipose tissue than that of the physically untrained students and patients. **Keywords:** THE BODY MASS INDEX, SELF-PERCEPTION OF WEIGHT, BODY COMPOSITION

The contemporary world is experiencing a marked increase in obesity and obesity-related diseases while the history of obesity, analyzed in terms of healing, represents a history of failure (1-4). WHO recommends as a screening modality for overweight and obesity, the body mass index method (5-7). The subjective self-perception of weight, more or less overlapping the actual nutritional state, can trigger a genuine psychopathology at all age groups (8). The body composition is used by health, fitness, clinical and school medicine experts. Regarding weight management, the estimation of the total amount of fat and fat-free mass can be used to determine the actual weight, to help formulate recommendations for diet and physical activity, to monitor the changes in body composition of those who participate in weight reduction or body remodeling programs.

The purpose of this paper is to analyze the body mass index in relation to the self-perception of weight and the body composition of three working groups composed of physically untrained young students, young athletes and patients diagnosed with chronic diseases.

MATERIAL AND METHODS

Material: The working groups were composed of 110 participants, divided into 3 groups: a group of untrained students 70.9% (78), a group of young athletes

15.5% (17) and a group of dialyzed patients 13.6% (15). In the sample, the gender distribution was: 50.9% (56) women and 49.1% (54) men. The participants' age ranges from a minimum of 19 and a maximum of 72 years, with an average of 26.03 years and a SD equal to 12.95.

Methods:

1. Determining the BMI (the body mass index)

The body mass index is calculated using other anthropometric measures, i.e. the weight (Silver Crest electronic scale) and height (stadiometer), using the following formula: BMI = weight / height^2.

The standard BMI classification and the degree of risk for co morbidities are presented in table I.

TABLE I
The standard BMI classification

Classification	BMI (kg/m^3)	The risk for co-morbities
Underweight	< 18.5	Moderate
Normal	18.5 – 24.9	Medium
Overweight	25 – 29.9	Slightly increased
Obesity class I	30 – 34.9	Moderate
Obesity class II	35 – 39.9	Severe
Obesity class III	>40	Extreme

2. The self-perception of weight. It was conducted within a population-based survey using a CORT 2004 questionnaire concerning health risk behaviors.

3. Evaluation of certain body composition elements. In order to have a complete picture of the body composition, of insufficient or fat excess and/or muscle deficiency on different segments of the body, we conducted a comprehensive evaluation of body composition using a multi-frequency bioimpedance method (InBody 720).

4. Processing advanced medical statistics. We used version 18 (2010) of the *SPSS* programme and the Kruskal-Wallis and Mann-Whitney tests for nonparametric data.

RESULTS AND DISCUSSION

1. The body mass index (BMI). The BMI from the group of untrained students varies between 16.43 and 37.77, with an average of 22.76 and a SD of 3.95. The BMI from the group of student athletes varies between 17.82 and 28.12, with an average of 22.22 and a SD of 2.89. The BMI from the group of patients varies between 18.42 and 35.11, with an average of 28.32 and a SD of 4.21 (tab. II).

The participants in this study can be divided according to the BMI as follows. A 9% (7) of untrained students are underweight, 66.7% (52) are normal weight and 24.4% (19) are overweight or obese. In the student athletes' group, 5.9% (1) are underweight, 76.5% (13) are normal weight and 17.6% (3) are overweight or obese. In the patients' group, 6.7% (1) are underweight, 13.3% (2) are normal weight and 80.0% (12) are overweight or obese (fig. 1).

TABLE II

The characteristics of the BMI descriptive analysis according to each group

BMI		Untrained students	Student athletes	Patients
N	Valid	78	17	15
	Missing data	0	0	0
Average		22.76	22.22	28.32
Medium		22.09	21.36	29.84
Standard deviation		3.95	2.89	4.21
Minimum		16.43	17.82	18.42
Maximum		37.77	28.12	35.11

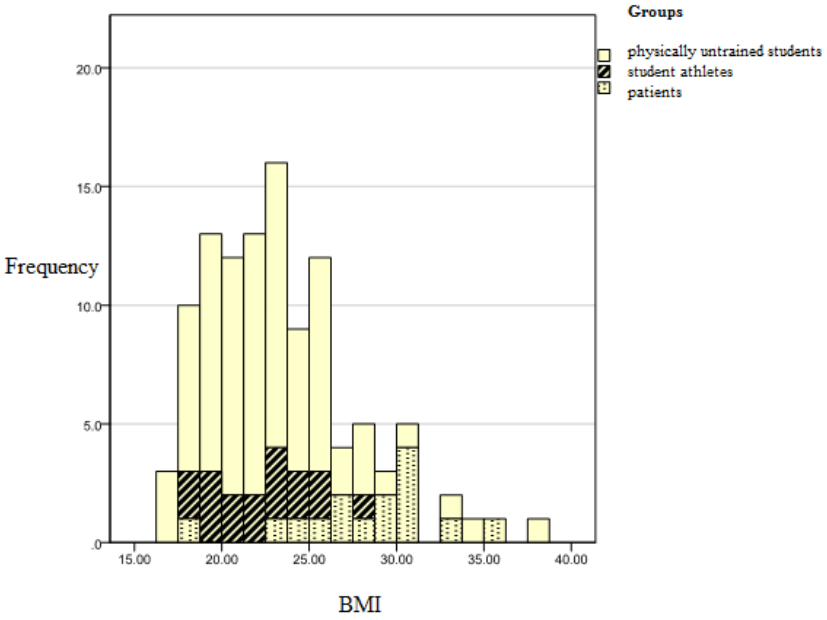

Fig. 1. The distribution of participants' histogram according to the BMI, for each group

2. The self-perception of weight. From the untrained students' group, 42.3% (33) consider themselves to be normal weight, 14.1% (11) think they are underweight and 43.6% (34) say they are overweight. In the student athletes' group, 58.8% (10) state they are normal weight, 17.6 (3) believe they are underweight and 23.5% (4) think they are overweight. In the patients' group, 46.7% (7) say they are normal weight, 6.7% (1) are underweight and 46.7% (7) believe they are overweight (fig. 2).

3. No significant differences were found between groups regarding the self-perception of weight, p>0.05. We found out that 59% of the untrained students, 58.9% of the athletes and only 33.3% of the patients correctly perceive their weight.

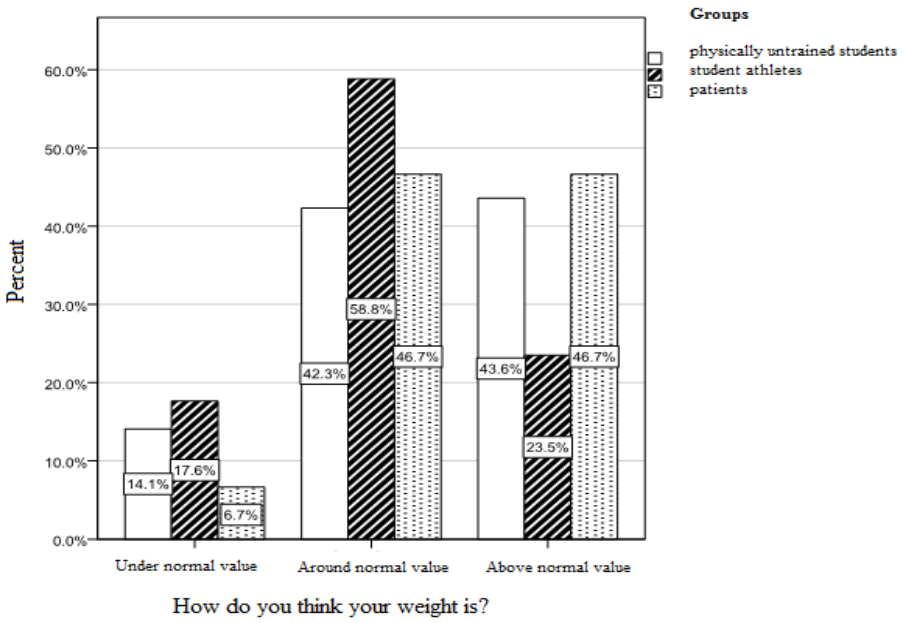

Fig. 2. The percentage distribution of participants according to their perception of weight, for each group

4. Body composition elements. ***The muscle tissue level*** is significantly different according to the perception of weight H (2) = 13.69, p<0.001. We have further investigated this difference and the level of statistical significance was reduced to 0,016 due to the Bonferroni correction. The muscle tissue level is significantly reduced at those who perceive themselves as overweight compared to those who consider their weight to be normal U=715, z=-3.05, p<0.01, respectively those who believe they are underweight U=173, z =-2.80, p<0.01. Among those who believe they are under normal weight and those who perceive themselves as normal weight, the differences in muscle tissue percentage are not statistically significant, p>0.016 (fig. 3).

The adipose tissue level is significantly different according to the perception of weight H(2)=25.43, p<0.001. We have further investigated this difference and the level of statistical significance was reduced to 0,016 due to the Bonferroni correction. The adipose tissue level is significantly higher at those who perceive themselves as overweight compared to those who consider their weight as normal U=610, z=-3.83, p <0.001, respectively those who perceive themselves as underweight U=99.5, z=-4.06, p<0.001. Those who perceive themselves as being under normal weight have a significantly lower adipose tissue level than those who perceive themselves as normal weight U=209.5, z=-2.57, p<0.01 (fig. 4).

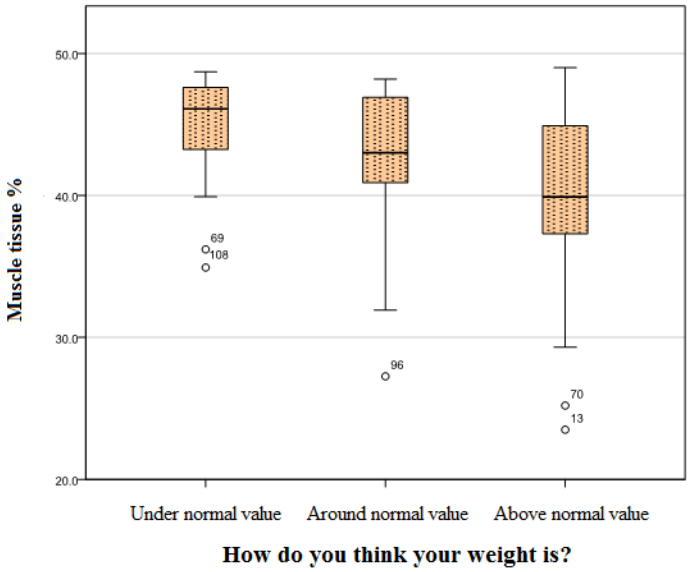

Fig. 3. The muscle tissue percentage distribution of the participants according to the perception of weight

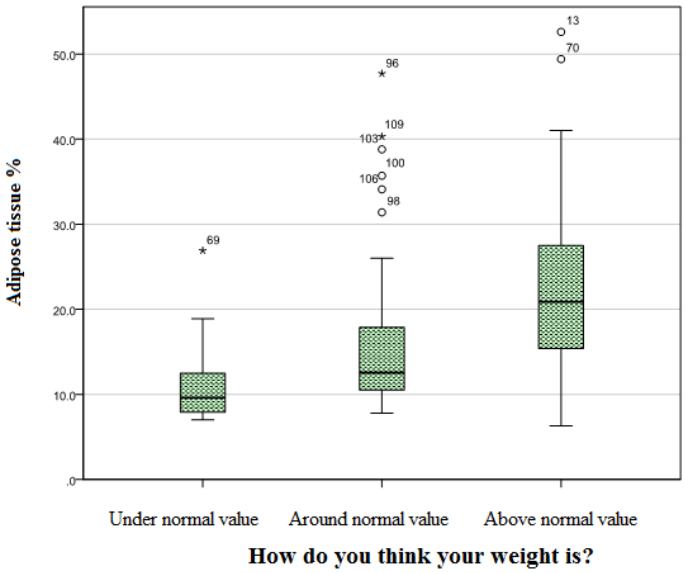

Fig. 4. The adipose tissue percentage distribution of the participants according to the perception of weight

Previous studies have shown that there is an association between the perception of weight and the obesity control methods, often independent from the actual weight

(9, 10).

In a recent study, Darlow et al. (11) have discovered that patients who perceived themselves as overweight and believed that being overweight is a health problem and who also had a family history of diabetes, had a higher risk of developing this disease. Patients with the same type of association, with obesity and a family history of cardiovascular diseases had higher chances of perceiving themselves as exposed to a higher development risk of various cardiovascular diseases.

CONCLUSIONS

The BMI of the patients is significantly higher than the BMI of the student athletes with a large size difference and with an average size difference than that of the untrained students. The differences between the group of untrained students and the student athletes group are not statistically significant, $p>0.05$. No significant differences between groups were found regarding the self-perception of weight.

Compared to the physically untrained students and patients, the student athletes have a significantly higher level of muscle tissue. The muscle tissue percentage of the patients is significantly lower than that of the physically untrained students. The muscle tissue percentage is positively correlated with the BMI in the student athletes' group and negatively correlated regarding the physically untrained students' group.

The student athletes have a significantly lower level of adipose tissue than that of the physically untrained students and patients. The adipose tissue percentage of the patients is significantly higher than that of the physically untrained students. The adipose tissue percentage is correlated with the BMI in the patients' group and the physically untrained athletes' group.

BORIC ACID IRRIGATION AS AN ADJUNCT TO MECHANICAL PERIODONTAL THERAPY IN PATIENTS WITH CHRONIC PERIODONTITIS

A group of researchers from the Department of Periodontology of Izmir University,Turkey realized a single-masked, randomized, controlled clinical trial whose purpose was to evaluate the effects of boric acid irrigation as an adjunct to scaling and root planing (SRP) on clinical and microbiologic parameters and compare this method with chlorhexidine irrigation and scaling and root planing alone in patients with chronic periodontitis. In the study were included forty-five systemically healthy patients with chronic periodontitis, divided into three groups: the first group *(C)* - scaling and root planing + saline irrigation; the second group *(CHX)* - scaling and root planing + chlorhexidine irrigation; the third group *(B)* - scaling and root planning + boric acid irrigation. A preclinical analysis was realized to determine an ideal concentration of boric acid. Clinical measurements (plaque index – PI , gingival index –GI , probing depth - PD, clinical attachment level - CAL, and bleeding on probing – BOP) were performed at baseline, 1 month, and 3 months after treatment. Subgingival plaque samples were also taken. Quantitative analysis of *Porphyromonas gingivalis, Tannerella forsythia,* and *Treponema denticola* was performed using real-time polymerase chain reaction (PCR) procedures. The concentration of boric acid was 0.75% in this study. All clinical parameters showed statistically significant reduction at all time points compared to baseline in all groups ($P < 0.001$). Whole-mouth PD and CAL reduction was similar in all groups at all time points after treatment ($P > 0.05$). The PD and CAL reductions for moderately deep pockets ($PD \geq 5$ and < 7) were greater in the B group compared to other groups between baseline and 1 month ($P < 0.05$). For deep pockets ($PD \geq 7$), reductions were similar in the B and CHX groups ($P > 0.05$). BOP (percentage) was significantly lower in the B group compared with the CHX and C groups in the first month after treatment ($P < 0.001$). GI and PI scores were significantly lower in the B and CHX groups compared with the C group at all time points after treatment ($P < 0.05$). The amounts of *Porphyromonas gingivalis, Tannerella forsythia* and *Treponema denticola* were significantly reduced in all treatment groups after 1 month ($P < 0.05$). No statistically significant differences were detected among the groups for microbiologic parameters at any time points after treatment ($P > 0.05$). The obtained data suggest that boric acid could be an alternative to chlorhexidine, and it might be more favorable because boric acid was superior in whole-mouth BOP as well as PD and CAL reduction for moderate pockets in early time periods. (Sağlam M, Arslan U, Buket Bozkurt S, Hakki SS. Boric Acid irrigation as an adjunct to mechanical periodontal therapy in patients with chronic periodontitis: a randomized clinical trial. *J Periodontol*, 2013; 84 (9):1297 – 1308).

INVERTED DUPLICATION DELETION OF 8P: CHARACTERIZATION BY STANDARD CYTOGENETIC AND SNP ARRAY ANALYSES

Adriana Sireteanu, Elena Braha, Roxana Popescu, Mihaela Gramescu, E.V. Gorduza, Cristina Rusu
University of Medicine and Pharmacy "Grigore T. Popa" - Iasi
Faculty of Medicine
Discipline of Medical Genetics

INVERTED DUPLICATION DELETION OF 8P: CHARACTERIZATION BY STANDARD CYTOGENETIC AND SNP ARRAY ANALYSES (Abstract): Inverted 8p duplication deletions are recurrent chromosomal rearrangements that most often arise through non-allelic homologous recombination (NAHR) during maternal meiosis between segmental duplications made up of the olfactory receptor (OR) gene clusters. The presence of a paracentric inversion polymorphism in 8p23.1, found in ~26% of European population, may trigger meiotic misalignment and NAHR between the OR gene repeats. We report clinical, cytogenetic, and molecular findings in a 4 year 8 month-old female with concomitant inverted duplication and terminal deletion of chromosome 8p. The girl, the first child of unrelated parents, was born at term, by normal delivery, after an uneventful pregnancy. Clinical examination revealed dysmorphic features, pectus excavatum, hypertonia, severe developmental delay. Brain ultrasound and MRI showed agenesis of the corpus callosum without other abnormalities. Conventional cytogenetic analysis identified additional material on chromosome 8 at band p21. SNP array analysis further characterized the abnormality as a duplication of about 31.3 Mb, from 8p23.1 to 8p11.1, and additionally revealed a terminal deletion of about 6.8 Mb, from 8p23.3 to 8p23.1. Genomic microarray also identified a region of disomy between deletion and duplication. Chromosome analysis of both parents revealed normal results. Based on clinical examination, conventional cytogenetics and SNP array, we established the diagnosis of inverted duplication deletion of 8p. SNP array analysis precisely defined the breakpoints of rearrangement and, by identifying a region of disomy between the duplication and deletion, indicated that NAHR between segmental duplications was the most likely mechanism for this type of abnormality. **Keywords**: INVERTED DUPLICATION DELETION OF 8P, SNP ARRAY, AGENESIS OF CORPUS CALLOSUM.

Inverted duplication deletion of 8p [inv dup del(8p)] is a recurrent chromosomal rearrangement first described in 1976 by Weleber et al. (1). It has an estimated prevalence of about 1:20,000 newborns (2), around 50 cases being reported worldwide.

Clinical manifestations include: intellectual disability (ID), agenesis of the corpus callosum, minor facial abnormalities, congenital heart defects, hypotonia with a tendency to develop progressive hypertonia and severe orthopedic problems (3, 4).

Inverted duplications with terminal deletions on 8p most often arise through NAHR during maternal meiosis between segmental duplications made up of OR

gene clusters (OR-REPD and OR-REPP). The presence of a paracentric inversion polymorphism in 8p23.1, found in ~26% of the European population, may trigger meiotic misalignment and NAHR between the inverted OR gene repeats (5).

We report the clinical, cytogenetic, and molecular findings in a girl with concomitant inverted duplication and terminal deletion of chromosome 8p and compare the phenotype of the patient with the cases reported in the literature, highlighting the importance of microarray technique in the identification of genomic disorders and their underlying mechanisms.

CASE PRESENTATION

The patient, a 4 year 8 month-old female, was the first child of non-consanguineous, healthy parents (mother - 31 years old, father - 37 years old at birth of the proband). There was no family history of ID, congenital anomalies or psychiatric disorders. Pregnancy was uneventful. She was born at term, by normal delivery, with a birth weight of 3,150 g, length of 50 cm and head circumference of 33 cm; Apgar score was 9 both at 1 and 5 minutes; physical examination revealed left parietal cephalohematoma and hypotonia. She presented neonatal seizures and cyanotic crises. Echocardiography showed a patent foramen ovale. Abdominal ultrasound, routine biochemical and hematological tests, as well as ophthalmologic examination and TORCH test were normal. No hearing impairment was identified. Brain ultrasound and MRI revealed agenesis of the corpus callosum without other abnormalities.

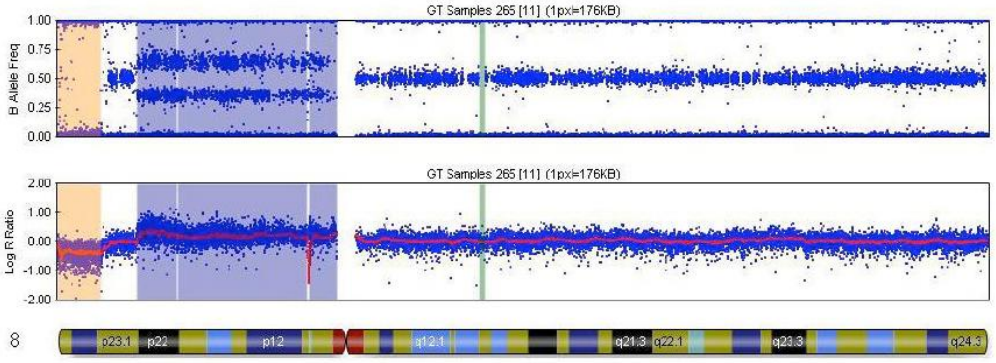

Fig. 1. SNP array results of chromosome 8 in the patient, showing a 6.8 Mb deletion in 8p23.3-p23.1 and a 31.3 Mb duplication in 8p23.1-p11.1

She achieved head control at 9 months and spoke her first word at the age of 12 months. Clinical examination at the age of 4 years and 8 months showed height of 106 cm (+0.43 SD), weight of 13.5 kg (-2.64 SD), and head circumference of 47 cm (-2.58 SD). She had facial dysmorphic features including square face, high forehead, hypoplastic zygomatic bones, large mouth, thin upper lip and everted lower lip, high palate and abnormal dental development, large ears, and dry, curly hair that receded from the temples. Other features were a short neck, pectus excavatum, slender arms and legs with long, tapering fingers, joint contractures in the legs and hips. She showed severe developmental and speech delay: she could not sit alone and she only said few single words.

Standard G banding chromosomal analysis identified an additional material on chromosome 8 at band p21: 46,XX,add(8)(p23.1). Parental karyotypes were normal. A SNP array was performed in University Medical Center Groningen using HumanCytoSNP-12 v 2.1 BeadChip platform (Illumina Inc., San Diego, CA) containing approximately 300.000 SNPs per sample. The data were processed using Genome Studio V 2010.1 software (Illumina). Genomic positions were defined using GRCh37/hg19. SNP array analysis detected a terminal deletion of approximately 6.8 Mb, from 8p23.3 to 8p23.1 (52,041-6,928,066), and a duplication of approximately 31.3 Mb, from 8p23.1 to 8p11.1 (12,599,114-43,951,038) (fig. 1). The deleted and duplicated regions contained 15 and 144 OMIM genes, respectively.

Based on clinical examination, conventional cytogenetics and SNP array, we established the diagnosis of inverted duplication deletion of 8p.

DISCUSSION

Our patient is severely affected compared with patients reported in the literature. The concomitant presence of deletion and duplication makes genotype/phenotype correlations difficult. Considering the size of the duplicated region and the large number of OMIM genes involved, the phenotypic findings in our patient are mainly due to duplication.

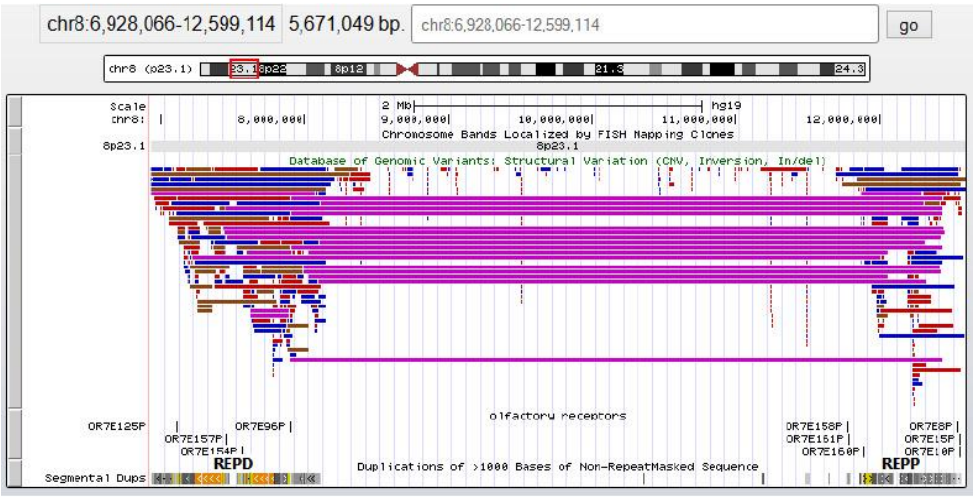

Fig. 2. Annotated screenshot of 5.6 Mb of band 8p23.1 (UCSC Genome Browser on Human Feb. 2009 Assembly (hg19), http://genome.ucsc.edu/). From bottom to top:
- segmental duplications that contain the OR repeats (labelled REPD and REPP);
- olfactory receptor genes based on The Human Olfactory Data Explorer (HORDE);
- multiple copy number variations of REPD and REPP in the Database of Genome Variants (sideways) and common polymorphic inversion between REPD and REPP (middle lines)

Three mechanisms may explain the formation of this abnormality: recombination within a paracentric inversion, recombination between inverted low copy repeats, or U-type exchange following a double strand break. All three mechanisms involve the formation of a dicentric chromosome 8 which subsequently breaks ei-

ther during a meiotic division or during early stages of embryonic development to produce an inv dup del(8p). Observation of a region of disomy between duplication and deletion can distinguish the U-type exchange from the other two mechanisms. The inv dup del(8p) in our patient can be explained by the second mentioned mechanism because the duplication was separated from the 8pter deletion by a ~5.6 Mb single copy region flanked by OR-REPD and OR-REPP regions (fig. 2). Stabilization of the broken chromosome ends can be achieved by: direct addition of telomeric repeats (''telomere healing'') (6); ''telomere capture'', in which broken chromosomes obtain the telomeric end of another chromosome (7); or by formation of a ring chromosome (8). Using high-resolution microarray no additional duplications could be identified, therefore in our patient the broken chromosome end of 8p has been stabilized by telomere healing.

The rearrangement is *de novo* as both parents had normal karyotypes. Dual colored FISH can be performed in the parents to investigate whether the meiotic recombination event among the OR gene clusters could have been stimulated by the presence of an inversion heterozygosity at 8p23.1. Even if inv dup del(8p) is a recombinant product of a parental 8p23.1 heterozygous inversion, there is no recurrence risk for this rearrangement and no invasive prenatal investigations are indicated for the next pregnancy.

CONCLUSIONS

In conclusion, microarray analysis permited precise molecular characterization of the rearrangement and indicated that NAHR between segmental duplications is the most likely mechanism for this abnormality. Also, it indicated that the terminal deletion was stabilized by telomere healing.

2. Department of Radiology and Medical Imaging, Emergency Hospital "Sf. Spiridon", Iaşi

COMPLEX UTRASOUND STUDY OF THE ATHEROSCLEROTIC PLAQUE (Abstract)**:** Carotid surgery concept is wining ground both among neurologists who recommend and vascular surgeons who perform an increased number of interventions. Regardless of the technique, we are interested in the tendency of the plaque to grow and determine stenosis. Ultrasound (US) is 91-94% sensitive and 85-99% specific in detecting a significant stenosis of the internal carotid artery. **Aim:** To establish a correlation between the preoperative US and intraoperative plaque characteristics in order to determine the restenosis rate. **Material and methods:** From January 1, 2012 to December 31, 2012, 70 consecutive patients were included in this study. Two groups were formed: 35 patients with stenotic ICA and 35 patients presenting stenosis at the femoral artery bifurcation (control group). The comparison between these two groups started from the premise of a similar pattern for internal carotid artery – deep femoral artery and external carotid artery- superficial femoral artery. US scans were performed on admission in all patients. All images were normalized and Gray Scale Median (GSM) was calculated. **Results:** Femoral plaque GSM values were higher in relation with hyperechogenicity highlighting the intensely calcified structure. Unstable plaques were more heterogenic, with higher transparency and lower GSM than stable plaques. This was the case of carotid plaques. During follow-up US revealed no restenosis. **Conclusions:** Femoral bifurcation plaques are calcified and determine chronic ischemic symptoms, while carotid bifurcation plaques are unstable and determine cerebral symptoms. US remain the gold standard non-invasive technique both for screening and diagnosis and set the therapeutic coordinates. **Keywords:** CAROTID PLAQUE, CAROTID ARTERY ULTRASONOGRAPHY, GRAY SCALE MEDIAN.

Carotid surgery concept is wining ground both among neurologists who recommend and vascular and cardiovascular surgeons who perform an increased number of interventions. Regardless of the technique used (open surgery, stenting) we were interested in the tendency of the plaque to grow and determine stenosis.

The prevalence of significant internal carotid artery (ICA) stenosis (more than 50%) is 0.5% among the age range 50 - 59 years, 10% in elderly over 80 years and 20% in patients presenting lower limb peripheral arterial disease (1).

Worldwide stroke is the third common cause of death. The prevalence of stroke after a transient ischemic attack (TIA) is 7% per year and the prevalence of stroke in an asymptomatic patient with a carotid stenosis larger than 80% is 3% per year (1).

The main cause of stroke is atheroembolism followed by the low blood flow through the stenosis.

The benefit from surgery in terms of stroke prevention in patients with symptomatic 70 - 99% stenosis (NASCET criteria) is higher than the one obtained from medical treatment (1). The available level I evidence suggests that in symptomatic patients surgery is currently the best option. The recommendation was based on a meta-analysis by The Cochrane Collaboration of eight randomized trials comparing carotid artery stenting with carotid endarterectomy (2). Patients with recent symptomatic stenosis (70-99%) are at highest risk of subsequent stroke. The efficacy of CEA falls with time (2).

Duplex ultrasound is the gold standard technique for carotid arteries evaluation. Ultrasound (US) uses B-mode US imaging and Doppler US to detect focal increases in blood flow velocity indicative of high grade carotid stenosis. The peak systolic velocity is the most frequently used to measure the severity of stenosis. Color Doppler technique increases the efficiency of the test, but it has not been shown to improve accuracy. US is 91-94% sensitive and 85-99% specific in detecting a significant stenosis of the ICA (3, 4, 5). Doppler US is also useful in obtaining information about plaque composition. Intraplaque hemorrhage, which may increase the risk of embolism and impact on prognosis, can be visualized on high resolution B-mode (3, 4, 5, 6, 7, 8). The ratio of ICA peak systolic velocity to the common carotid artery (CCA) velocity predicting a high grade stenosis sets the indication for surgery (9).

MATERIAL AND METHODS

The patients entering this study were selected from: patients referred by neurology departments with a high probability of advanced ICA lesion, patients with peripheral vascular disease already hospitalized in the vascular surgery department screened positive for significant carotid or femoral stenotic lesions, patients with arteriopathy hospitalized in cardiology and internal medicine departments diagnosed with significant femoral artery stenosis. 98% of the patients were diagnosed and selected in the Vascular Surgery Department. Before surgery all patients benefited from a new Doppler US (performed on Siemens Echo-Doppler XP 300 Premium - 2010).

All patients gave their informed consent for the study.

Two groups were formed: patients with stenotic ICA and patients presenting stenosis at the femoral artery bifurcation. The inclusion criteria for the first group were: asymptomatic ICA stenosis greater than 70%, history of TIA, history of minor stroke with self-sufficiency and 50-95% ICA stenosis. The patients in the second group meet the following inclusion criteria: arteriopatathy stage III and IV with atherosclerotic lesions at the femoral bifurcation, regardless of the chosen surgical procedure.

The exclusion criteria were: autoimmune diseases, hypothyroidism, osteoporosis, hepatic insufficiency (GOT higher than 2.5 U / l), chronic kidney disease (creatinine above 2.0 mg / dl), ischemic heart disease class III, IV NYHA, atrial fibrillation and malignancies.

The comparison between these two groups started from the premise of the existence of a similar pattern for ICA – deep femoral artery (DFA) and external carotid artery (ECA) - superficial femoral artery (SFA). Thus, the bifurcation of the

CCA into the ICA and ECA anatomically resembles the bifurcation of common femoral artery (CFA) into DFA and SFA at each bifurcation there is an artery that will face increased resistance (ECA and SFA) and an artery that faces low resistance in the periphery (the ICA and DFA). Because of this, plaques at the two bifurcations are supposed to have a similar structure. Although clinically the manifestations of obstruction/stenosis of the ICA are much more severe than in obstruction/stenosis of DFA, the two models can be studied together in terms of atheromatous plaque progression.

US scans were performed on admission in all patients in both groups. B-mode settings were adjusted and then saved to ensure uniformity throughout the study (fig. 1). The stenosis grade was measured both in transversal and longitudinal section (fig. 2, 3).

Fig. 1. ICA and CCA B - mode US

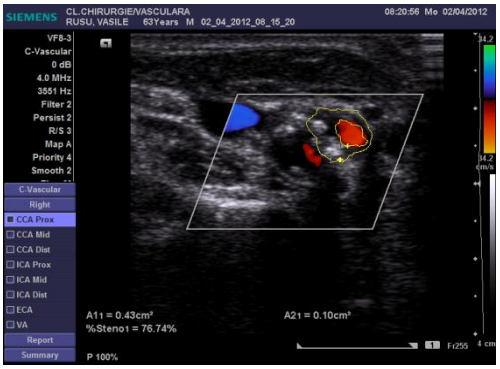

Fig. 2. Stenosis measurement on transversal section

Fig. 3. Stenosis measurement on longitudinal section

Two reference points were used for normalization of B-mode images, blood (black), and adventitia (white). Patients were examined supine with the neck-rotated 45 degrees to the opposite side. A peripheral vascular transducer was used. The image was "frozen", stored and transferred to a computer in order to calculate the Gray Scale Median (GSM). All images were normalized according to the method proposed by El-Atrozy et al. eliminating sonographic gain-induced variability of echogenicity in which the entire image is changed by a process of linear scaling to two reference points (blood and adventitia) with computer software (Adobe Photoshop 7.0). The GSM of the blood was set to 0, and the GSM of adventitia was set to 255. To determine the GSM for each stenotic plaque we acquired the histogram (10, 11, 12, 13, 14) (fig. 4, 5).

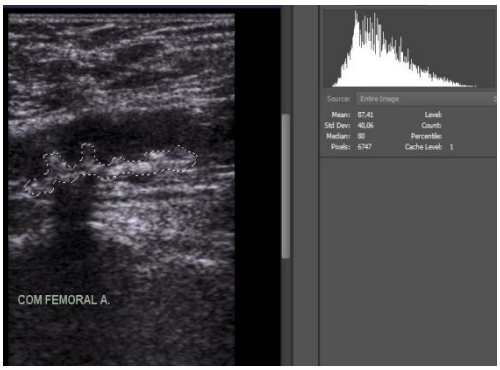

Fig. 4. Selected atherom plaque and prenormalized histogram

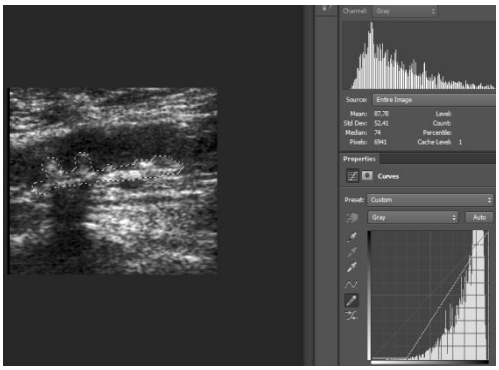

Fig. 5. Selected atherom plaque and normalized histogram

The results were used to compare the groups with one another and to draw conclusions from each group.

All patients underwent surgical interventions (endarterectomy and angioplasty in the patients with carotid artery stenosis or femoral artery stenosis and endarterectomy associated with bypasses in the patients with femoral artery stenosis)

US was performed postoperatively and as follow-up at 1, 3, 6, 9 and 12 months (fig. 6,7).

Fig. 6. Follow-up US - carotid angioplasty

Fig. 7. Follow-up: carotid angioplasty Dopper US

RESULTS

From January 1, 2012 to December 31, 2012 we included in the study 70 consecutive patients meeting all criteria, 35 patients in each group.

Twelve patients with carotid lesions showed ICA stenosis greater than 90% stenosis. Patients with femoral lesions had CFA stenosis greater than 50% associating in 13 cases DFA stenosis greater than 70%.

No statistically significant differences in demographic characteristics, vascular risk factors or therapy were identified.

Post-Hoc analysis (paired analysis) comparing the femoral or carotid plaque area before and after the normalization

revealed the absence of statistical difference. The difference between prenormalization and normalization GSM values in each group were statistically significant (tab. I, II).

The average carotid plaque area was twice as big as the average femoral plaque area (tab. III).

Femoral plaque GSM values were higher in relation with hyperechogenity, highlighting the intensely calcified structure.

Unstable plaques were more heterogenic, with higher transparency and lower GSM than stable plaques.

Carotid plaques average GSM was lower than the femoral one, meaning the carotid plaques are less stable.

Minimum-maxim differences reveal a high grade of heterogenity in both groups (tab. IV).

Patients showed no carotid or femoral restenosis during the 1, 3, 6 and 12 months of US follow-up. Patients remained under surveillance.

DISCUSSION

Our study showed higher GSM values than those reported in the literature (15, 16). This is a consequence of the patients' tendency to present to the vascular surgeon in advanced disease stages.

The correlation of a lower GSM with plaque instability needs to be proved. During the US follow-up we aim at detecting the occurrence of restenosis.

CONCLUSIONS

Bifurcation plaques occurring in peripheral atherosclerotic disease are calcified and determine chronic ischemic symptoms (intermittent claudications, rest pain), while carotid bifurcation plaques are unstable and determine cerebral symptoms either by TIA or ischemic stroke. US remain the gold standard non-invasive technique both for screening and diagnosis and set the therapeutic coordinates. The GSM analysis is a new and versatile tool used to establish plaque characteristics and to assess the risk for acute events.

NEWS

NEW GENE INVOLVED IN ANEMIA

Some forms of congenital anemia are caused by the deficiency in heme biosynthesis. Heme is a constitutive element of hemoglobin that is a protein in red blood cells responsible for transporting oxygen. Americans researchers have discovered a new gene that regulates heme biosynthesis. This gene named mitochondrial ATPase inhibitory factor 1 (Atpif1) is involved in the enzymatic activity of ferrochelatase, the terminal enzyme in heme biosynthesis. Using an animal model, the researchers found that loss of Atpif1 reduces ferrochelatase activity and increases mitochondrial pH which leads to deficiency in heme biosynthesis and causes anemia. Understanding of the mechanisms regulating heme biosynthesis may contribute to development of improved therapies for certain type of anemia such as congenital sideroblastic anemia and mitochondrial disease (Shah DI, Takahashi-Makise N, Cooney JD *et all*. Mitochondrial Atpif1 regulates haem synthesis in developing erythroblasts. *Nature*. 2012; 491(7425): 608-12).

EARLY RETROPANCREATIC LAMINA DISSECTION DURING PANCREATICO-DUODENECTOMY: HOW, WHEN AND WHY? (Abstract):Pancreaticoduodenectomy is the procedure of choice for tumors of the pancreatic head and periampullary region. During pancreaticoduodenectomy, early neck division may be inadequate in case of hepatic artery anatomic variants, suspected involvement of the superior mesenteric vessels or intraductal papillary mucinous neoplasms. **Material and methods:** We describe our early approach to the superior mesenteric vessels during pancreaticoduodenectomy, by retroportal lamina dissection before pancreatic transection. **Results:** We used this approach in 41 patients. There were 28 patients with abnormal hepatic artery, which was spared in 26 cases. Hepatic artery reconstruction was required in 2 cases. Nine patients with intraductal papillary mucinous neoplasms underwent 6 pancreaticoduodenectomiesextented to the body and 3 total pancreaticoduodenectomies. Four patients with adenocarcinoma involving the portomesenteric vein required pancreaticoduodenectomy with venous resection and reconstruction. **Conclusions:** Early retropancreatic lamina dissection is useful way to tailor a pancreaticoduodenectomy which is recommended in selective indications. **Keywords**: PANCREATIC SURGERY, TECHNIQUE, HEPATIC ARTERY, SUPERIOR MESENTERIC ARTERY.

Pancreaticoduodenectomy (PD) is the treatment of choice for tumors of the pancreatic head and periampullary region. Since the first PD performed by Whipple in 1937, more than 65 improvements of the technique were made, concerning mainly pylorus preservation or reconstruction of pancreatico-digestive continuity. Standard PD is usually performed backward, with transection of the pancreatic neck before the superior mesenteric artery (SMA) dissection. Recently, indications of PD have extended to intraductal papillary mucinous neoplasms (IPMN) and periampullary tumors invading the mesentericoportal vein. In these last two conditions, division of the pancreatic neck may be inappropriate so division of the body can be preferred. We perform in such cases, as well as in hepatic artery (HA) variants, a PD with early retropancreatic lamina dissection (RPLd), close to the origin of the SMA, to readily assess

variant pattern of the arterial blood supply to the liver and radicality of resection, to perform mobilization of the specimen before pancreatic division, and, if necessary, to safely perform venous clamping. RPLd was first suggested by Pessaux (1). The purpose of the current study is to describe how, when and why we perform PD with RPLd.

MATERIAL AND METHODS

One hundred thirty six consecutive patients underwent PD for periampullary and pancreatic head tumors between January 1, 2007 and December 31, 2011. Among them, 41 (22 males and 19 females, median age 59 years, range 44-78), underwent PD with early RPLd. Twenty eight patients have been preoperatively assessed by multidetector computed tomography with HA anomalies and 4 with adenocarcinoma involving the portomesenteric axis. IPMN have been preoperatively assessed by abdominal multidetector computed tomography and endoscopic ultrasound with guided fine needle aspiration. Twenty cases had RHA arising from SMA (18, replaced=11 or accessory=7) or Ct (2 cases of replaced RHA). Eight cases had a RCHA originating in SMA.

TECHNIQUE

Surgical exploration must be completed by intraoperative ultrasonography. The pancreas head exposure is obtained by an extended Kocher maneuver, incision of the attachment of the transverse mesocolon to the right perinephric area, and opening of the lesser sac by separating the greater omentum from the transverse colon. The superior mesenteric vein (SMV) is exposed where it lies to the anterior third duodenum (fig. 1).

Dorsal to the pancreas, the dissection must pass beyond the aorta, to get full posterior mobilization of the duodenopancreas to the left, and to distinguish the plane between the SMV and the SMA. Liver and peritoneal exploration is performed as well as the palpation of the mesenteric root and biopsy examination of aortocaval nodes with frozen section.

The retropancreatic dissection is carried on downwards from the inferior border of the Winslow foramen along the Treitz fascia, exposing the inferior vena cava on its left side, the left renal vein with its upper margin and in between, the origin of the SMA (fig. 2, 3).

The SMA origin is isolated in this angle, and then, along the plane of its adventitia, the RPL, which is inserted on its right aspect, is dissected and removed “step-by-step” in a frontal plane behind the pancreas (fig 4). This dissection is achieved along 3-4 cm, from the SMA origin until its entrance into the mesentery, after progressive exposure and gentle medial retraction of the portal vein (PV), which is also set free from the RPL (fig 3, 4).

RPL is retracted rightwards and the lymphatic tissue between SMA and SMV is removed. The possible SMA invasion is early detected, due to RPL involvement, avoiding the risk for nonradical resection. Such exposure allows easier dissection of a right HA (RHA) originating from SMA or celiac trunk (Ct) or a replaced common HA (RCHA) coming from the SMA. This vessel, which arises 1-2 cm beneath the SMA origin, is looped and freed from the RPL, upwards to the hepatic pedicle. To facilitate the SMA and aberrant RHA or RCHA dissection, the doudenopancreas is retracted en bloc upwards, ventrally and to the left (Fig 3). Limited dissection along the right

side of the SMA (fig. 4) is advocated, to avoid an extensive removal of the perivascular nervous plexus, resulting in postoperative intestinal motility troubles.

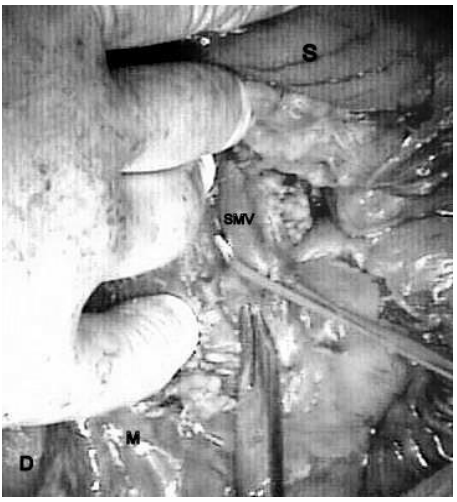

Fig. 1. Exposure of the SMV on the anterior third duodenum

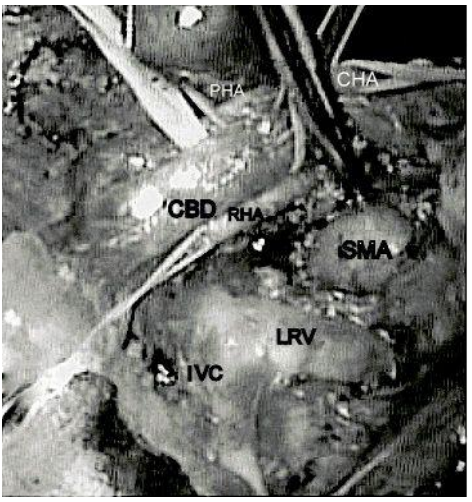

Fig. 2. Retropancreatic dissection with a replaced RHA originating in SMA before RPLd and common bile duct division

Fig. 3. Retropancreatic dissection: the duodenopancreas with the tumor is retracted medially and to the left

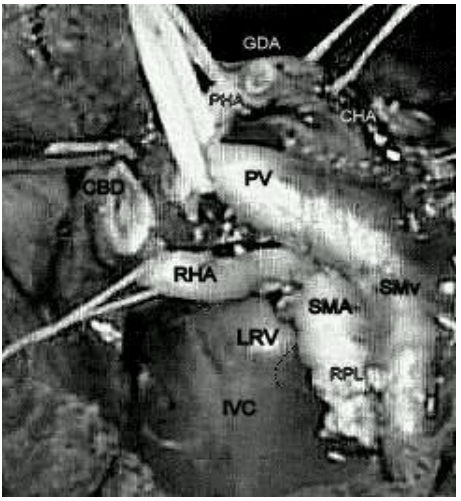

Fig. 4. Intraoperative image just before pancreatic transection; the SMA was set free from the RPL along 3-4 cm

At this point the hepatic pedicle is dissected. After cholecystectomy, the common and proper HA are isolated, when they exist as such. The right gastric vessels are divided, the gastroduodenal artery is identified and clamped to ensure that the arterial

flow either in hepatic and gastric arteries remains normal and there is no unrecognized Ct stenosis. The gastroduodenal artery is divided, as well as the common bile duct above the entry of the cystic duct. This improves the exposure of the supra-pancreatic PV. Care must be taken during lymphadenectomy around the PV to an accessory or replaced RHA originating from the SMA or Ct, but also to a RCHA from the SMA. This vessel runs upwards behind the PV and we loop it. The SMV is entirely dissected at the inferior pancreatic margin with ligation of the right gastroepiploic vein and of all veins draining the uncinate, which is exposed up to the right side of the SMA. At this stage the posterior wall of the portomesenteric vein is entirely exposed. The Treitz ligament is divided, equally by a posterior approach, allowing mobilization of the duodeno-jejunaljonction and its retraction beneath the superior mesenteric vessels, so the specimen to be removed reaches the right side of the mesenteric root. The inferior pancreaticoduodenal artery is identified and ligated. Once the radicality of PD is established jejunal and distal gastric division is performed according to Whipple procedure. The last step of the resection phase is the pancreatic neck transection, just in front of the PV. When pancreatic division must be performed on the body, we divide the dorsal pancreatic artery and collaterals of both the SMA and the SMV (from the inferior edge of the pancreas). In case of involvement of the portomesenteric confluence, we control the splenic vein behind the body. Adequate mobilization of the mesentery and right colon is necessary to perform safely *,"en bloc"* resection and venous reconstruction. We estimate this mobilization as useful in case of limited portomesenteric invasion, in order to avoid vein grafting during venous reconstruction. In case of IPMN extending from the head to the body, we carry on the retro-pancreatic mobilization towards the left and dissect the splenic vessels with successive ligation of their collaterals. When the pancreatic body is mobilized enough from the splenic vessels, we can divide the pancreas at any level, or entirely remove it if necessary. Frozen section analysis is performed on the cut surfaces, to assess the malignant status of the remnant pancreas. The reconstruction phase, drains placement and postoperative care are similar to those from standard PD.

RESULTS

The aberrant vessel was preserved in 26 (63.41%) cases. A RCHA originating from the SMA was involved by an enlarged lymph nodes mass behind the pancreatic head in 2 patients. A segmental resection of the involved RCHA had to be performed with arterial reconstruction, using the reversed splenic artery. Four patients with ductal adenocarcinoma involving the portomesenteric confluence required en bloc resection, mobilization of the right colon and mesentery root followed by mesentericoportalveno-venous suture. We reimplanted the splenic vein into the PV in all cases. When vascular reconstruction was required, clamping time did not exceed 22 minutes. Anastomotic patency and normal blood flow were confirmed by Doppler ultrasound at the end of the procedure.

The same approach was used in 9 patients with IPMN (6 PD extented to the body- IPMN in the head, neck or uncinate, and 3 total PD - IPMN diffusely involving the pancreatic duct). Mean operative time over all the 41 patients was 315 minutes

and mean blood loss 430 ml. The mean hospital stay was 16.5 days. There were no early complications particularly related to this approach. For the malignant tumors, a R0 resection was achieved in 24 (58.54%) patients and a R1 in 2 (involvement of the RPL). The median survival time was 25.8 months. The follow-up lasted until patient death or until the cut-off date of January 31, 2012. At the time of the last follow-up, 29 (70.73%) patients were still alive.

DISCUSSION

Because of recent decrease in mortality rate, PD is now routinely performed for tumors of the pancreatic head and periampullary region, but also for IPMN or periampullary tumors invading the mesentericoportal vein. We have described herein our technique of early RPLd during PD on the right side of the SMA, before the digestive and pancreatic continuity should be interrupted. We consider this technique particularly suitable in case of HA abnormality, with RHA originating from SMA or Ct, or RCHA from the SMA, suspected involvement of the SMA, IPMN extended from the pancreatic head to the body and involvement of the portomesenteric vein.

Standard PD includes the creation of a tunnel between the pancreatic neck and the PV, followed by neck transection. The pancreatic continuity is interrupted before radicality of the resection could be assessed close to the SMA. Even in some recent series, nonradical PD represents 9 to 25 % cases (2). Moreover, in the standard PD, dissection of a RHA or RCHA is usually performed late, when bleeding from the resection specimen decreases the exposure of the SMA and of an aberrant RHA. Early neck transection is not suitable when the neck is involved, as in tumors involving the portomesenteric vein or in IPMN extended to the body. One of the difficulties of PD is variability of peripancreatic vessel anatomy (3). Assessment of variant pattern of the arterial blood supply to the liver in patients who are about to undergo a PD avoids unnecessary complications, as fatal hepatic injury. Accidental ligation of aberrant HA may result in hepatic necrosis, ischemic biliary injury or anastomotic complications (4). The importance of sparing this artery during PD lies not so much in preventing hepatic ischemia, but in preventing a breakdown of bilioenteric anastomosis, because the blood supply to the cranial part of the common bile duct is entirely dependent on the RHA after PD. Preoperative assessment of coelio–mesenteric vascular pattern (variants, strictures) is of the utmost importance for the surgeon. RHA or RCHA from SMA may course behind, within the pancreas head, or along its ventral side (5).

Ductal carcinoma with venous limited involvement can be safely resected with a long-term survival similar to that observed after radical resection without venous involvement (3). In this situation, venous resection is best performed *"en bloc"* to obtain disease-free margins. This approach results in the tumor being attached only to the involved veins so clamping of the portomesenteric confluence is easier and shorter. Mobilization of the right colon and mesentery root are useful to avoid vein grafting during reconstruction of the PV (6). It is expected that, because pancreatic transection is performed at the end, congestion and bleeding are less likely whereas the venous drainage of both the specimen and bowel are compromised minimally during most of the procedure (7).

In case of IPMN, the most frequent localization is the pancreatic head, but in-

volvement of the body may occur to some patients (8). In this setting and particularly in malignancies, en bloc resection requires pancreatic division of the body. The final transection of the pancreas can be performed at the desired place if it is enough mobilized from the splenic vessels, preventing tumor opening, which might disseminate cancer into the abdomen. Furthermore, dissection along the splenic vessels can be extended up to the splenic hilum allowing splenic preservation if the whole pancreas must be resected (8).

In conclusion, early RPLd is useful technique to expose the retropancreatic-mesenteric vasculature during PD. We advocate this approach in selective situations, such HA anatomic variants, suspected SMA involvement, limited invasion of the mesentericoportal axis and IPMN. RPLd also standardizes the radicality of PD and allows earlier vascular control. Further prospective studies are required to assess its advantages over standard PD, since there is no consensus worldwide.

CERVICAL INCOMPETENCE ASSOCIATED WITH CONGENITAL UTERINE MALFORMATIONS (Abstract): Cervical incompetence is basically a cervix that is too weak to stay closed during a pregnancy. It is generally categorized as premature opening of the cervix without labor or contractions. **Aim:** To estimate the incidence of incompetence of the uterine cervix at patients with congenital uterine malformations. **Material and methods**: Our study was a retrospective and prospective one between 2002 and 2009. We evaluate the length of the cervix by transvaginal ultrasonography during the second trimester of pregnancy**. Results:** We had 316 cases with congenital uterine malformations. From these we found 49 (15.3%) women with incompetence of the cervix: 8 (2.5%) with unicornuate uterus, 11 (3.4%) with bicornuate uterus and 30 (9.5%) cases uterus with septum. For all these wad made cerclage when we found funneling of the cervix or the cervix was open less than 4 cm. The use of ultrasonography has been very helpful with the diagnosis, and is made when the cervical os (opening) is greater than 2.5 cm, or the length has shortened to less than 20 mm. All patients had preterm delivery. **Conclusions:** When we have cases with congenital uterine malformations we must think that incompetence of the cervix could be associated, so we must assess the status of the cervix for these patients by serial ultrasound examinations starting between 16 and 20 weeks of gestation. Our patients had preterm delivery caused not only the incompetent cervix, but the malformation of the uterus is implicated also. **Keywords**: CERVICAL INCOMPETENCE, CONGENITAL ULTRASONOGRAPHY, GESTATION.

Cervical incompetence is related with 15 - 20% of abortions appeared in the second quarter of pregnancy. The incidence of congenital uterine malformations (Cg.UM) in the general population and among women with recurrent pregnancy loss is not clearly known. Although the reported incidence is 0.16 to 10%, recent data suggest that it is 1% in the general population and 3% in women with recurrent pregnancy loss and adverse reproductive outcome (1, 2).

Cervical incompetence (CI) due to Cg.UM has as a consequence premature birth which in turn is associated with 75% of perinatal morbidity and mortality. Two thirds of premature infants are the result of labors between 26 and 32 weeks of pregnancy and are marked by the highest rate of mortality, respiratory distress, intraventricular hemorrhage, necrotizing enterocolitis, developmental delay, visual and

hearing deficit and chronic lung diseases (1).

Effective methods for detecting preterm birth can avoid unnecessary interventions and treatments in women without risk (2). It is well-known the necessity of a suitable cervical length in order to maintain a normal pregnancy, and length and diameter of the cervix must remain steadily as pregnancy progresses, both in primiparous and multiparous.

In women with low risk, cervical length (CL) is 35-40 mm at 40 weeks of pregnancy; the lower limit is 25 mm and 50 mm the higher. Hibbard (cit. 2) detected the presence of a CL of 38.5 + 8 mm at 20 weeks of pregnancy. The progressive shortening of CL occurs naturally after 30 weeks in normal full term pregnancy patients (3).

A length less than 25 mm is abnormal before 24 weeks, with a risk of premature birth under 35 weeks of 4% in low-risk population and a positive predictive value (PPV) of 18%, but for pregnant women at high risk, the incidence of premature birth increases to 26% and PPV to 55% (4).

MATERIAL AND METHODS

The study consisted of 49 cases with a lot cervical incompetence (CI) selected from 316 patients with congenital uterine malformations (Cg. UM) and assisted Municipal Hospital, Radauti, Suceava County, during 2002-2009. This subset analysis showed a rural origin for 31 (63.3%) cases as compared with urban, 18 (37.7%); with occupational relationship represented by 41 (83.6%) patients employees, 7 (14.3%) households and 1 (2.1%) other categories. Age group 25-33 years represented 31 (63.3%) of total cases (fig. 1).

Distribution by age groups in relation to birth type indicated a significantly higher frequency ($p < 0.05$) for the natural way: 36 (73.4%) *vs.* 13 (26.6%) cases by caesarean section (fig. 2).

By the age of 33, prevailed full term births (75.6%), when 93.7% were primiparous and by 2.1% - bi, tri and multiparous (fig. 3).

Referral to marital status of the entire group of 49 patients with CI, 39 (79.5%) were married, 14.3% divorced, 4.1% in concubinage, and 2.1% other (fig. 4).

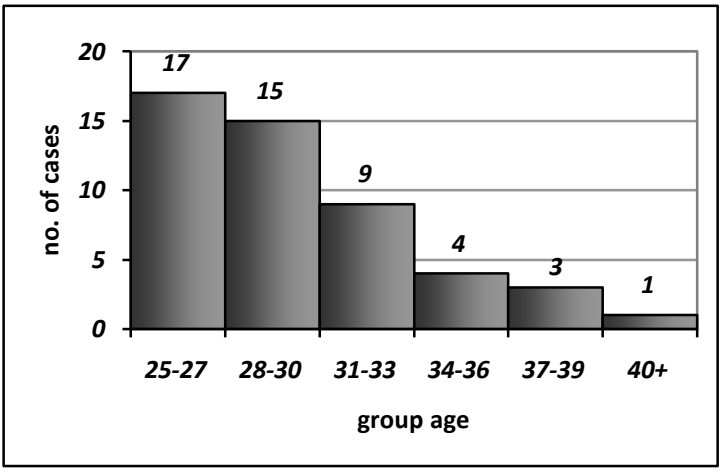

Fig. 1. Age histogram

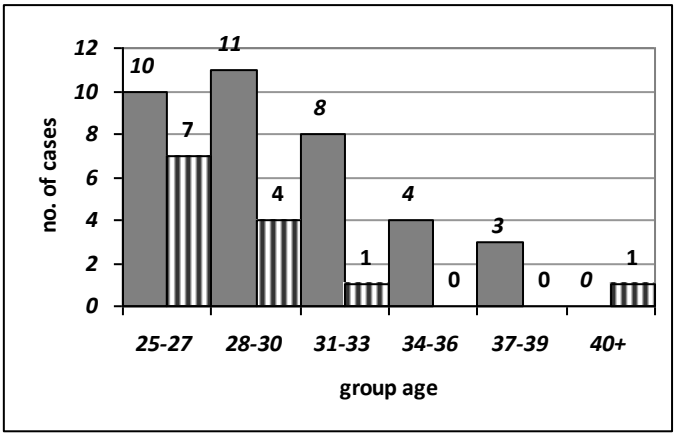

Fig. 2. Age-related delivery type

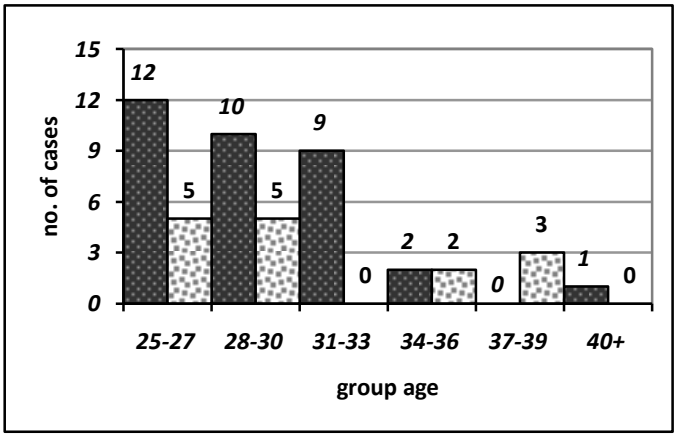

Fig. 3. Age-related full and preterm delivery

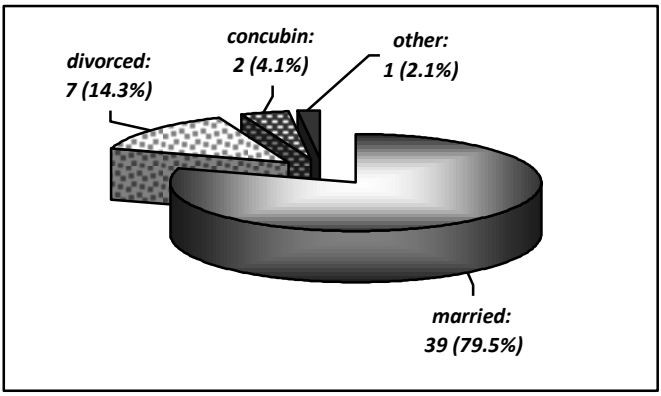

Fig. 4. Patients' marital status

Gynecological medical history was recorded in 47 (95.8%) of cases and other categories had low values (2.1%).

Patients received abdominal and vaginal ultrasound, ensuring a good view of the internal cervical os (ICO) and measurement of the cervical length (CL).

Incompetent cervix diagnosis was achieved by highlighting the funneling, expansion and protrusion of membranes, the ICO aspects of *Z*, *V* and *U*, respectively. If funneling highlighted, its width and length was measured, a closed LC, as well as the proportion of funneling and cervical index, calculated by the formula: funneling length +1 / cervix length. Incompetent cervix risk assessment in patients with Cg.UM was performed between 16-20 weeks (fig. 5).

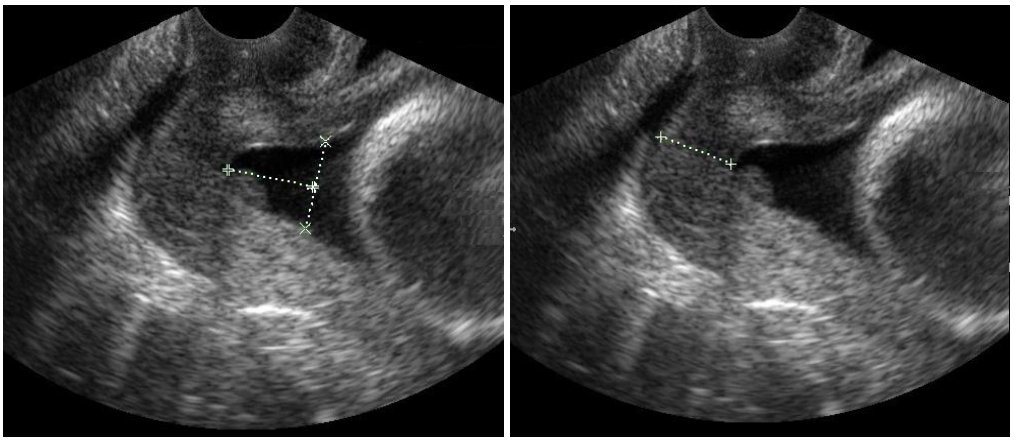

Fig. 5. Funneling measurement - diagnosis at 18 weeks

RESULTS

The ultrasound evaluation of the 49 women with CI showed that 15.5% were diagnosed with incompetent cervix, 30 (61.2%) had septated uterus, 11 (22.4%) bicornuate, and 8 (16.3%) unicornuate uterus (fig. 6).

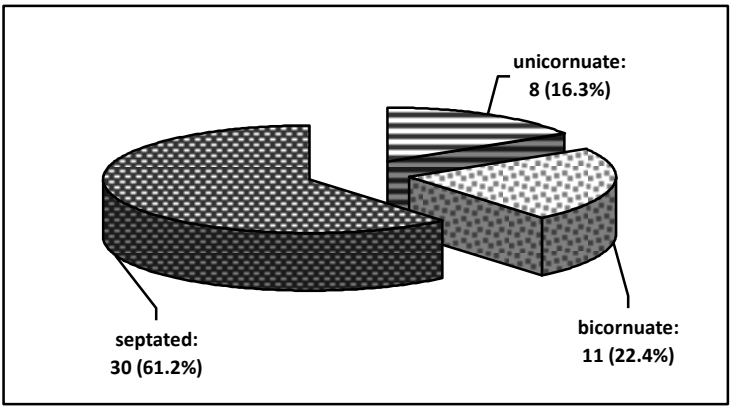

Fig. 6. Types of malformed uterus diagnosed with cervical incompetence

When the diagnosis of CI was established for all studied pregnant women, cervical cerclage was performed by Mc Donald technique (7). After performing cerclage, the patient remained under surveillance in order to detect any occurrence of uterine contractions and after discharge was advised bed rest to reduce pressure on the cervix thereby increasing the chances of maintaining the pregnancy until the fetus becomes viable. In the study group, no funneling appeared after cerclage and all patients delivered prematurely at a gestational age between 28 and 35 weeks (tab. I). The largest number of patients who delivered after 32 weeks had septated uterus - 22 (45%) pregnant women. It was noticed that CL should be correlated with other risk factors such as vaginal infections because a shortened cervix is less resistant to infection ascension, with the risk of amniotitis.

TABLE I

Gestational age at birth correlate with the type of uterine malformation

UTERINE MALFORMATION					
SEPTATED		**BICORNUATE**		**UNICORNUATE**

3	34				
3	35				
30		**11**		**8**	

*PA – weeks of gestation

From the group of patients with Cg.UM and incompetent cervix, 35 cases were natural delivery, proving that the malformed uterus and incompetent cervix are not indications of cesarean section (fig. 7).

The risk of premature birth was assessed based on clinical criteria, a score including maternal and social risk factors, and especially on the digital vaginal examination. These elements can be associated with biochemical factors, including the presence of fetal fibronectin in the cervix, its absence being an indicator with negative predictive value of premature birth in the next 7-14 days.

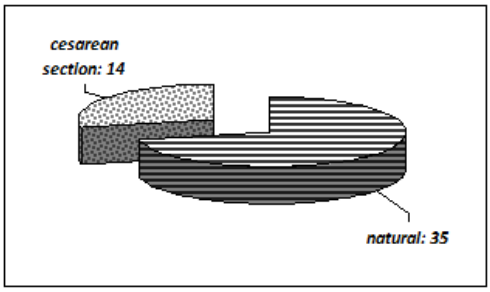

Fig. 7. Type of delivery (number of cases)

DISCUSSION

On endovaginal ultrasound in patients at risk of premature birth, NP-risk, CL is only 50% of <25 mm between 10-14 weeks. Ultrasound is performed at 18-22 weeks, in order to notice the presence of cervical shortening or funneling, with the ability to relieve the risk of premature birth in 70% of cases, as compared with 40% when screening is done at 19-24 weeks (5).

For the studied group, ultrasound was performed between 16-20 weeks. CL measurement has proved useful in deciding cerclage necessity, improving the pregnancy evolution only if previous 3 or 4 premature births are in antecedents. The ultrasound follow-up indicates that 25-30% of patients develop funneling after cerclage (6). In our study, none of the patients showed funneling after cerclage.

Iams (7) followed pregnancy patients with malformed uterus (septated, unicornuate, bicornuate), between 24 and 28 weeks and found that less a CL than 25 mm was two times more frequent than pregnancy of normal uterus.

Endovaginal ultrasound represented the most effective way for assessing the condition of cervical status, because it allows better visualization of the ICO. A high pressure may pseudo increase the cervical length, hiding thus funneling (dilation of the ICO).

CONCLUSIONS

Our study enabled the assessment of premature birth risk in patients with cervical incompetence due to congenital uterine malformations, highlighting that the endovaginal ultrasound, performed in the second trimester of pregnancy is the most effective method. Thus, a cervical length <25 mm and funneling over 50% of the total length of the cervix were associated with an increased risk of premature birth.

On the other hand, determining the diagnosis of incompetent cervix in optimal time, allowed the cervical cerclage intervention and the progress of pregnancy until the fetus was viable.

IMPORTANCE OF POSTURE ASSESSMENT IN ANKYLOSING SPONDYLITIS. PRELIMINARY STUDY (Abstract): **Aim:** The aim of this study is to perform a screening of patients diagnosed with ankylosing spondylitis (AS) in order to evaluate the static spinal disorders and correlate the results with the main clinical and functional parameters that characterize this disease. **Material and methods:** Ninety-five patients diagnosed with AS according to the 1994 New York criteria were screened, and 68 of them (all males) presenting static spinal disorders and on physical therapy programs in different outpatient physical therapy units throughout 2011 entered the study. **Results:** The distribution of the patients according to static spinal disorders was almost even. There were no statistically significant differences in mean age and disease duration ($p>0.05$). The assessment of lumbosacral pain in the morning (VAS1) and daytime lumbosacral pain (VAS2) showed a higher scores in patients suffering from kyphoscoliosis than in those with scoliosis ($p=0.020$), ($p=0.000$), or kyphosis**.** Ott and modified Schöber index, and chest expansion, had higher mean values in patients with scoliosis compared with the other postural disorders ($p<0.001$). Statistically higher mean BASFI values were recorded in patients with kyphoscoliosis ($p=0.038$), while the mean BASMI values were lower in scoliosis patients ($p<0.001$). As to the quality of life of AS patients, HAQ-DI index recorded significantly lower mean values for kyphoscoliosis compared with other postural disorders ($p<0.001$). **Conclusions**: Our study suggests that posture assessment and implicitly the correction of possible misalignments should be part of the kinetic physical therapy program. Rigorous observing of postural recommendations can prevent the respiratory system complications. **Key words**: POSTURE, KYPHOSIS, SCOLIOSIS, KYPHOSCOLIOSIS.

Ankylosing spondylitis (AS) is a chronic, progressive inflammatory disease, seriously affecting the musculo-skeletal disorders, especially in younger patients, and causing serious disabilities (1-3). Mobility and deformity are parameters which sometimes evolve independently (4).

Changes in the spine start early in the first 10 years of disease (5), the patient adopting such inappropriate positions as poking head neck, thoracic hyperkyphosis, lumbar lordosis deletion with hip flexion and internal rotation and knee flexion (6). Depending on patient activity, such changes

can cause various degrees of disability, significantly affecting the quality of life (7).

In AS patients posture is often affected early after the onset or as the disease progresses (8-10), and this should be taken into account in the rehabilitation treatment.

A poor body physical structure should be detected, assessed both with respect to its magnitude and consequences, and eventually corrected. Posture, determined by the reports of musculoskeletal components, is the main objective of the assessment. It was believed that a perfect body posture and a good relation between its segments are synonymous with 'physical beauty' (11).

The aim of this study is to perform a screening of patients diagnosed with AS in order to evaluate the static spinal disorders and correlate the results with the main clinical and functional parameters that characterize this disease.

MATERIAL AND METHODS

Ninety-five patients with AS were screened (New York criteria, modified for AS), of which only 68 male patients which followed outpatient physiokinetic treatment in various medical rehabilitation units in Iasi town in 2011 entered the study. Study exclusion criteria were: patients presenting sindesmofites in the cervical-dorsolumbar spine, were under biologic drug treatment, and presented other conditons with axial involvement (Scheuermann disease, sacroiliac osteochondrosis, spinal stenosis, herniated discs, and congenital abnormalities)

Patients were assessed according to a standard protocol that included: (i) general data (age, disease duration), (ii) clinical and functional parameters (visual analogue scale for morning lumbosacral pain (VAS1) and daytime lumbosacrate pain (VAS2), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), values recorded on a scale of 0-10 (0 -normal, 10 -severe); lumbar spine mobility (Schöber's modified test and finger-to-floor distance (FFD), dorsal spine mobillity (Ott index), thoracic spine flexibility (chest expansion) and quality of life Health Assessment Questionnaire (HAQ-DI, score that ranges from 0 -impossible and 30 -normal); (iii) static spinal disorders assessed by "lead wire" test and anthropometric data (Table I).

For statistical analysis we used SPSS 13.0 software. Descriptive data were presented as mean ± standard deviation (SD). Distribution of all variables was assessed using the nonparametric Kolmorov-Smirnov test. Student t-test and χ^2 test (chi-square) were used to assess homogeneity of subgroups of patients with vertebral static disorder. A $p<0.05$ value was considered statistically significant.

RESULTS

Patient distribution in relation to static spinal disorders was almost even. Patients with AS, were aged between 18 and 31 years; mean age 24.32 ± 3.36 years. In relation to the type of static spinal disorders, patients'mean age did not differ significantly (p=0.417), the same being true for disease duration (p=0.913) (tab. I, fig. 1).

Morning lumbosacral pain (VAS1) and daytime lumbosacral pain assessment (VAS2) gave significantly higher scores in patients with kyphoscoliosis than in those with scoliosis (p=0.020) or kyphosis (p=0.000).

As to FFD and BASDAI indices, no significant differences between the types of spinal disorders were found (p=0.108), (p=0.069) respectively.

TABLE I

Demografic, clinical, functional, and quality of life data in AS patients

Characteristics	Mean ± SD	Lowest	Highest
Age (years)	24.32 ±3.36	18	31
Disease duration (years)	4.79 ± 2.70	1	10
VAS1 (range 0-10)	3.91±1.218	2	5
VAS2 (range 0-10)	2.66±1.087	0	4
BASFI (range 0-10)	3.37±1.97	0.4	6
BASMI (range 0-10)	3.49±723	2	4
BASDAI (range 0-10)	5.22±1.95	2.1	7.6
Ott index (cm)	2.52±1.167	1	5
Modified Schöber (cm)	2.46±85	1	4.5
FFD (cm)	-17.24±9.841	-33	-5
Chest expansion (cm	2.56±79	1.5	5
HAQ-DI (range 0-30)	25.88±2.209	23	29

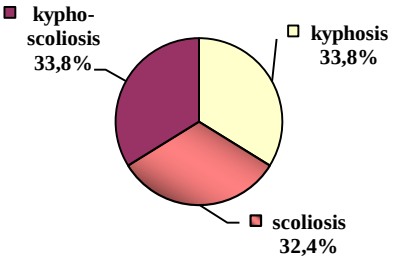

Fig. 1. Distribution of vertebral static disorders

Spinal mobility, assessed by Ott and modified Schöber indices, and chest expansion index showed higher mean values in patients with scoliosis compared with other types of vertebral static disturbance ($p<0.001$).

The functional BASFI index had significantly higher mean values in patients with kyphoscoliosis as compared with those with scoliosis or kyphosis ($p=0.038$), and mean BASMI was significantly lower in patients with scoliosis ($p<0.001$).

As to the quality of life of AS patients, HAQ-DI index had significantly lower mean values in patients with kypho-scoliosis as compared with the other types of static spinal disorders ($p<0.001$) (tab. II).

TABLE II

Correlation between vertebral static disorders and clinical and functional parameters in AS patients

Parameters	Kyphosis (mean ±DS)	Scoliosis (mean ±DS)	Kyphoscoliosis (mean ±DS)	p
VAS1	3.35±1.229	4.14±1.125	4.26±1.137	0.020
VAS2	1.74±810	2.64±658	3.61±839	0.000
BASFI	3.12±2.12	2.78±1.87	4.20±1.69	0.038
BASMI	3.91±288	2.59±503	3.91±288	0.000
BASDAI	4.83±2.06	4.82±1.93	5.98±1.69	0.069
Ott index	2.00±71	3.82±91	1.80±60	0.000
Modified Schöber	2.74±58	3.00±79	1.70±56	0.000
FFD	-15.65±9.890	-15.23±8.530	-20.74±11.128	0.108
Chest expansion	2.22±56	3.20±77	2.24±60	0.000
HAQ-DI	26.39±2.105	26.86±2.054	24.43±1.727	0.000

DISCUSSION

In this study, posture assessment revealed what are the onset static spinal disorders (preankylosing spondilitis), which, with disease progression, lead to severe clinical outcomes that aggravate the disease-generated general dysfunctional process (12).

The main feature of AS is its progression to ankylosis by the replacement of inflammation with bone formation (13). Given this, the unbalanced use of muscles, ligaments and joint will faster lead to poor posture by the inflammation of overused tissues (4).

It is known that the treatment of AS substantially contributes to preventing postural deformities (14, 15). In AS, pain and stiffness are symptoms are inflammation-related that can last as long as 10 years (5). In our study, the patients with kyphoscoliosis experienced more pain (VAS1 and VAS2).

One characteristic of AS is the loss of spinal mobility and less frequently of peripheral joint mobility (5). In this study the patients were thus selected as to allow differentiation of spinal mobility according to the spinal static disorders. Thus, modified Schöber index showed higher mean values in patients with scoliosis as compared to those with kyphosis and kyphoscoliosis, demonstrating the fact that first it is noticed the dissapearance of physiologic lumbar lordosis (by reduced mobility of the lumbar spine) and then kyphotic deformation (4).

Chest impairment in AS is due to changes in the spine and inflammatory process in small joints of the rib cage (thoracodynia) (4). Thus, in our study the lowest Ott index values, and implicitly a lower chest expansion, were found in patients with kyphosis and kyphoscoliosis with repercussions on the quality of life (HAQ-DI), especially in the patients presenting kyphoscoliosis.

BASDAI index was accepted as a standard tool for assessing disease activity in recent years (16, 17). In our assessments, no significant differences in BASDAI score between the different types of spinal disorders were recorded ($p=0.069$). However, this supports the suggestion that poor posture in AS equally affects the clinical disease activity in the different types of static spinal disorders.

Some aspects of functional capacity are often affected in patients with AS (18, 19). In our study, BASFI had significantly higher mean values in patients with kyphoscoliosis than in patients with scoliosis or kyphosis ($p=0.038$), BASMI showed significantly lower mean values in patients with scoliosis ($p<0.001$).

CONCLUSIONS

Posture assessment as part of the initial or check-up consultation of AS patient revealed a tendency towards antalgic or inadequate postures. This has allowed us a better understanding of the clinical and functional aspects of the patient with onset AS.

Based on these results, our study suggests that posture assessment and implicitly the correction of possible misalignments should be part of the kinetic physical therapy program. Rigorous observing of postural recommendations can prevent the respiratory system complications.

KNEE OSTEOARTHRITIS, DYSLIPIDEMIA SYNDROME AND EXERCISE (Abstract). The **aim** of our study was to evaluate the influence of aerobic training on the dyslipedemia in patients with knee osteoarthritis (KOA)**. Material and methods:** Prospective observational six-month study performed on 40 patients with KOA, fulfilling the inclusion criteria, classified according to their participation in specific aerobic training program (30 minutes/day, 5 days/ week) in two subgroups. A standard evaluation protocol was followed assessing lipid parameters (total cholesterol, triglycerides, LDL-cholesterol, HDL-cholesterol levels) at baseline, three and six months. Statistical analysis was performed in SPSS 16.0, $p<0.05$. **Results:** Subgroup analysis has demonstrated a statistical significant improvement in plasma lipids levels in all patients performing regular aerobic training (cholesterol, triglycerides, HDL-cholesterol, LDL-cholesterol) ($p<0.05$). Although the difference reported for total cholesterol, triglycerides and LDL-cholesterol after six months between subgroups was not significant ($p>0.05$), the mean level of HDL-cholesterol was significantly higher in patients performing aerobic training, reaching the cardio-vascular protective levels. **Conclusions:** Regular aerobic exercise has a positive effect on plasma lipoprotein concentrations; further research is needed for the assessment of long-term effects of physical exercises for both KOA and lipid pattern. **Key words:** KNEE OSTEOARTHRITIS, DYSLIPIDEMIA SYNDROME, EXERCISE.

Knee osteoarthritis (KOA) is recognized as a degenerative joint disease, characterized clinical by chronic pain, enlargement and deformity of joints leading to muscle atrophy, decreased mobility, gait abnormalities, physical disability and impaired quality of life. It is widely accepted that the complex therapeutically algorithm is actually based on pharmacologic, surgical and kinetic approach. Strengthening, stretching/range of motion and aerobic training are commonly involved in improving symptoms and physical functioning (1,2). As the confirmed risk factors associated with osteoarthritis are female gender, obesity, age, speculation continues about the role of other reported risk factors such as hypercholesterolemia, high levels of glucose and hypertension, the protective effect of current use of estrogens in postmenopausal women (3,4).

Dyslipidemia defined as abnormal blood lipids levels, has a major role in the devel-

opment and progression of atherosclerotic plaque conducting to major cardiovascular risk. Exercise and diet are used in the prevention and management of dyslipidemia (5,6).

It is well known as hypercholesterolemia, hypertriglyceridemia and low HDL-cholesterol are some of the major cardiovascular risk factors. Those parameters seem to be in association with osteoarthritis, moreover having a role in their progression as revealed by many studies. Significant radiological changes were found in unilateral knee osteoarthritis with elevated blood glucose levels and moderately elevated serum cholesterol levels while bilateral knee osteoarthritis is associated with hypertension and elevated cholesterol (7).

In muscle occurs increase the activity of lipoprotein lipase and oxidize non-esterified fatty acids in response to training exercise. Physically active individuals have decreased levels of total plasmatic cholesterol with higher levels of HDL1- and HDL2-cholesterol, lower levels of VLDL- and LDL-cholesterol and reduced triglycerides (8).

The aim of our study was to evaluate the influence of aerobic training on lipid profile in patients with knee osteoarthritis**.**

MATERIAL AND METHODS

We have performed a prospective observational study on 40 patients diagnosed with KOA who were admitted in the Rheumatology Department, Clinical Rehabilitation Hospital of Iasi, Romania, between 2010 and 2011. All patients fulfilled the inclusion criteria as follows: (i) the American College of Rheumatology diagnostic criteria for clinical knee osteoarthritis, (ii) radiographic evidence of grade I to III tibio-femoral or patello-femoral KOA (Kellgren-Lawrence grading system), (iii) sedentary activity pattern and (iv) willingness to undergo a kinetic program. Patients were divided into two groups (20 patients each group), equally distributed by age and gender, according to their participation in the aerobic exercise training comprising 30 minutes of walking per day, five days per week for a period of six months.

Patients with recent knee surgery/ arthroscopy and other conditions that contraindicate physical training, as well as undergoing lipid-lowering drugs were excluded from our study.

A standard evaluation was performed in all cases, including the following parameters at baseline (visit 1), after three months (visit 2) and six months (visit 3): total cholesterol levels (reference values 110-200mg / dl), serum triglycerides (reference values 50-150mg/dl), LDL-cholesterol (reference values 70-130mg/dl) and HDL-cholesterol (38-75mg/dl reference values).

Statistical data processing was performed in SPSS 16.0 software, both descriptive (mean $\pm$ standard deviation) and analytical tests (t-student, Mann-Whitney, Wilcoxon, Kolmogorov-Smirnov) being used in subgroup analysis. The level of statistical significance was set at $p<0.05$ for all tests.

RESULTS

Baseline characteristics of all patients are shown in table I. Although both groups were comparable for demographic data (sex ratio, age), weight, body mass index, a statistically significant difference was demonstrated for all parameters of lipidic metabolism ($p <0.05$). Therefore we selected the first group (group A) to perform the kinetic program as they presented higher abnormalities in lipidic pattern.

*Total cholesterol***.** Statistically **s**ignificant improvement of cholesterol level was de-

tected after three and six months of aerobic training as compared to baseline in all patients with KOA undertaking regular exercises (mean cholesterol level: 224.88 mg/dl at visit 1, 218.45mg/dl at three months, 213.05 mg/dl at six months) ($p<0.05$).

TABLE I
Baseline characteristics of patients with knee osteoarthritis

	Group A	Group B	p
Age* (years)	58.45	57.15	0.531
Cholesterol (mg/dl)	224.88	206.07	0.048
Tryglicerides (mg/dl)	134.88	127.30	0.014
LDL-chol (mg/dl)	136.15	126.02	0.025
HDL-chol (mg/dl)	43.94	46.50	0.048
Weight (kg)	89	82.4	0.186

*mean

On the other hand, we have demonstrated a significant increase in the mean cholesterol level in patients from group B in whom aerobic program was prohibited ($p<0.05$), the upward trend being reflected by the following average values of total cholesterol: 206.07 mg/dl at baseline, 217.40 mg/dl at visit 2 and 210.45mg/dl at the last visit (fig.1).

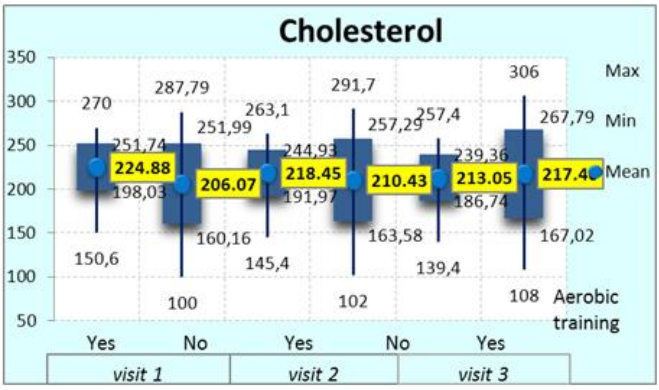

Fig.1. Monitoring of cholesterol in knee osteoarthritis subgroups

*Triglycerides***.** Furthermore, we analyzed triglycerides levels in both groups. A statistically significant decrease has been demonstrated in patients performing aerobic training (mean triglycerides: 134.89 mg/dl at visit 1, 124.42 mg/dl at visit 2 and 116.99 mg/dl at visit 3), while in group B mean triglycerides had a significant upward slope (127.30 mg/dl at baseline, 130.39 mg/dl at three months, 133.39 mg/dl at six months) (fig. 2).

LDL-cholesterol. A progressive decrease in the mean LDL-cholesterol level was demonstrated during the all visits in patients with KOA performing exercises (136.15 mg/dl at visit 1, 127.80 mg/dl at visit 2 and 123.87 mg/dl visit 3). Moreover, the difference in LDL-cholesterol between visits was

also statistically significant (p=0.0001). Compared with patients completing regular aerobic exercises, the mean LDL-cholesterol in patients with KOA in which the aerobic training was not allowed showed a slight increase (126.02 mg/dl at baseline, 128.90 mg/dl at visit 2, and 130.92 mg/dl at visit 3) (fig. 3) .

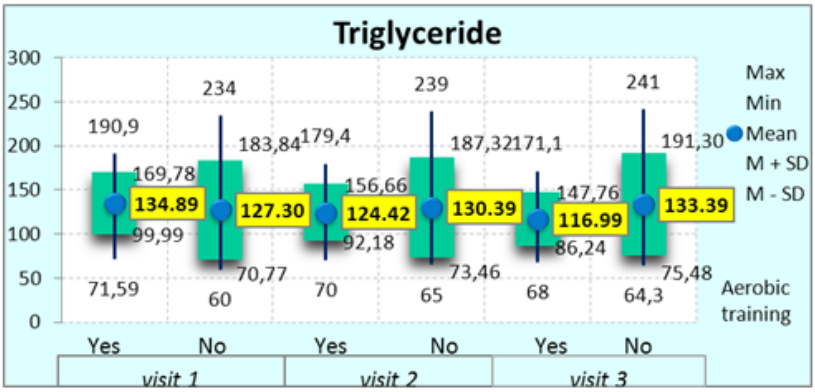

Fig.2. Monitoring of triglycerides in knee osteoarthritis subgroups

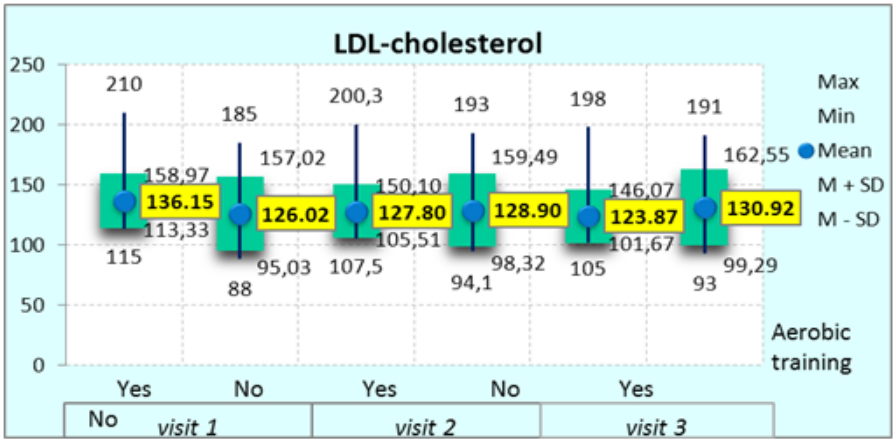

Fig. 3. Monitoring of LDL-cholesterol in knee osteoarthritis subgroups

HDL-cholesterol. **A** progressive increase in the HDL-cholesterol level was reported in patients with performing training over the course of all three visits (43.94 mg/dl at visit 1, 50.03 mg/dl at visit 2 and 57.68 mg/dl at visit 3). The difference between visits was statistically significant (t-Student, p= 0.0001).

Conversely, a progressive decrease in HDL-cholesterol in the second subgroup was observed from baseline (45.1 mg/dl at visit 1, 46.50 mg/dl at visit 2 and 44.56 mg/dl at visit 3).

Figure 4 shows the mean HDL-cholesterol levels in different time points for both groups. A statistical significant difference was registered between groups after six months (p=0.0001).

Weight. We have registered a progressive

decrease in KOA patients completing regular aerobic exercises (89 kg at visit 1, 87.1 kg at visit 2 and 84.7 kg at visit 3), with significant difference in mean weight values at visit 2 and visit 3 (p<0.0001). In contrast, for KOA patient without training weight levels have a upward trend (82.4 kg at baseline, 83.9 kg at visit 2, 85.9 kg at visit 3) (fig 5).

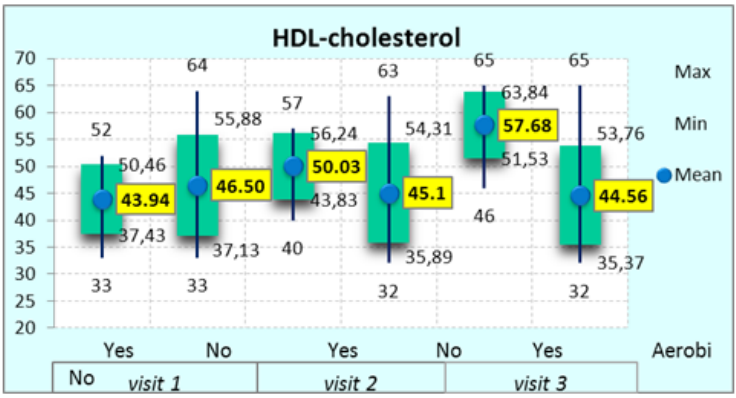

Fig. 4. Monitoring of HDL-cholesterol in knee osteoarthritis subgroups

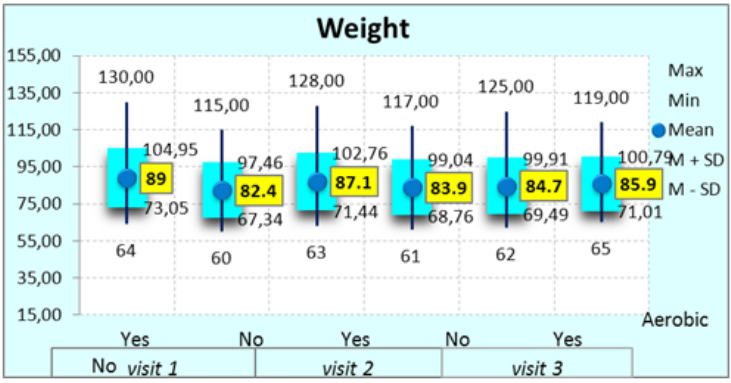

Fig. 5. Monitoring of cholesterol in knee osteoarthritis subgroups

DISCUSSION

Results of the present study suggest that regular aerobic exercise training lowers all the classic lipidic metabolism parameters including: cholesterol, triglycerides, LDL-cholesterol and weight, increasing in the mean time HDL-cholesterol values.

Regarding the intimate mechanism of aerobic training on lipidic metabolism data is lacking in current literature. Some studies proved a connection between weight loss and variation of all lipidic profile parameters (triglycerides, cholesterol, LDL-cholesterol and in HDL-cholesterol concentration) (9,10, 11).

Various studies report changes in serum lipids in different percentages. In general, it was observed that high levels of aerobic activity are accompanied by high levels of HDL-cholesterol. Thus, it was observed that in overweight people with low serum levels of HDL-cholesterol, physical activity in-

creases HDL-cholesterol (12,13).

It is known that exercise has a greater impact on lipid spectrum for women than for men. In our case we encountered no difference, both sexes presenting the same changes in serum lipids.

Effects of exercise on lipids are directly proportional to the duration and intensity of the performed effort. It is widely recognized that aerobic activity such as brisk walking, jogging, swimming, bike riding, or cross-country skiing, loss weight by decreases excess fat and fat-positive change (14,15).

CONCLUSIONS

Regular aerobic exercise appears to have a positive and comparable effect on plasma lipoprotein concentrations. Statistical significant difference was found for HDL fraction reflecting the benefit of aerobic training on cardio vascular risk factors profile. Exercise may be the most efficient way to achieve optimum results in knee osteoarthritis treatment, improving general health status. Further research is needed for the assessment of long-term effects of physical exercises for both KOA and lipid pattern.

UNILATERAL OPTIC NEURITIS ASSOCIATED WITH INFLUENZA IN ADULT. CASE REPORT (Abstract): The term optic neuritis refers to inflammation of the optic nerve due to many causes, characterized by subacute unilateral loss of vision, periocular pain and impaired color vision. Optic neuritis can be caused by idiopathic inflammatory demyelination, autoimmune diseases, infectious causes (bacterial, viral, fungal), tumors or ischemic diseases. A few cases of optic neuritis caused by influenza infection have been reported. We report the case of a 51-year-old woman that came to our clinic complaining of a sudden decrease in visual acuity following an episode of flu. The fundus of her left eye showed optic nerve edema. Based on the medical history, fundus appearance, optical coherence tomography, visual field and laboratory investigations (magnetic resonance imaging, blood tests), the diagnosis of optic neuritis associated with influenza was made. **Keywords**: OPTIC NEURITIS, INFLUENZA, CORTICOTHERAPY.

The term of optic neuritis (ON) refers to inflammation of the optic nerve due to many causes, characterized by unilateral painful vision loss. Patients with ON typically complain of the triad of subacute unilateral loss of vision, periocular pain and impaired color vision (1). The pathogenesis of ON is not well understood. It is likely due to some inflammatory processes which lead to delayed type-IV hypersensitivity reaction induced by the released cytokines and other inflammatory mediators from activated peripheral T-cells which can cross the blood-brain barrier and cause destruction of myelin, neural cell death and axonal degeneration (2). In most individuals, ON is caused by idiopathic inflammatory demyelination. This may occur as an isolated syndrome or in association with multiple sclerosis (MS). Approximately 50% of patients with isolated ON develop definite MS within 15 years (3). Nonetheless, inflammatory ON may also be caused by other autoimmune diseases such as sarcoidosis, systemic lupus erythematosus, Sjogren's syndrome or Behcet's disease. Although infectious causes of ON such as herpes Zoster, Lyme disease, syphilis, tuberculosis or toxoplasmosis are rare, they should be kept in mind because a specific treatment is required rapidly (4). Many other conditions such as tumors or ischemic diseases can also cause ON. Based on the location of involvement, ON can be categorized as: 1. retrobulbar neuritis with

normal optic disc appearance; 2. papillitis with swollen disc; 3. perineuritis, which involves the optic nerve sheath while the optic disc may or may not be swollen;4. neuroretinitis with optic disc edema and macular star exudates.

CASE REPORT

We report the case of a 51-year-old woman who came to our clinic complaining of sudden decrease in visual acuity (VA). The patient had a history of flu, with fever, cough and discrete myalgia 2 weeks prior to the ophthalmological problem. She received a treatment with high dose acetaminophen and ibuprofen.

On examination, the best corrected VA was 10/10 for the right eye (RE) and 1/10 for the left eye (LE). Slit lamp examination of the anterior segment of the eye was within normal limits. The fundus of each eye was examined after tropicamide-induced mydriasis and revealed a normal fundus in the RE and optic nerve edema in the LE. In the LE we noticed a protruding and congested optic nerve head, with peripapillary hemorrhage, narrowed arteries and dilated veins and in the lower part of the macula a yellowish nodule (fig. 1).

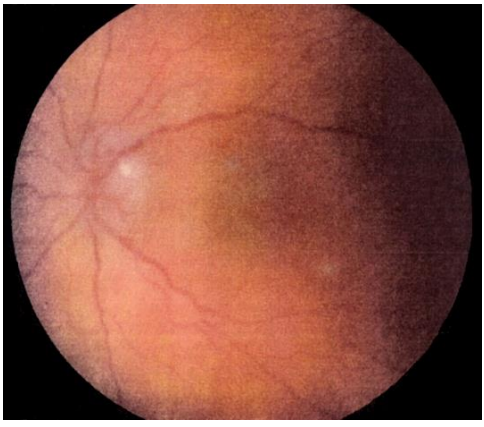

Fig. 1. Left eye fundus - optic nerve edema

Fluorescein angiography revealed normal arterial and venous filling, no delay in disc filling, but late optic disk leakage (fig. 2, 3). The macular nodule showed delayed filling and discrete late phase leakage.

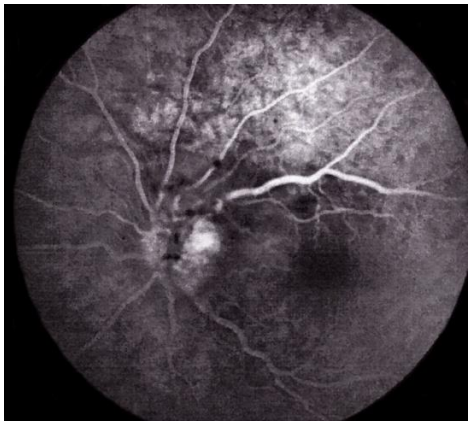

Fig. 2. Angiofluorography-normal vascular filling

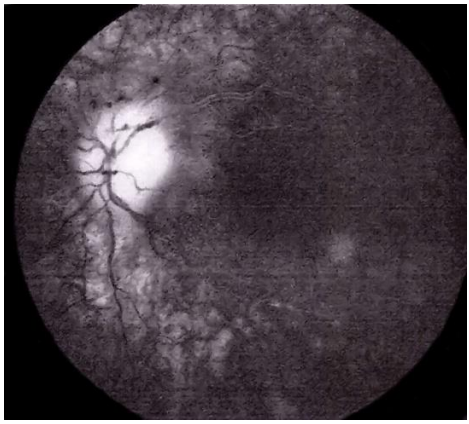

Fig. 3. Angiofluorography – optic disc leakage

Optical coherence tomography (OCT) revealed swollen optic nerve, thickening of the peripapillary retinal nerve fiber layer (RNFL) in the superior, nasal and inferior quadrants (fig. 4), and normal macular thickness.

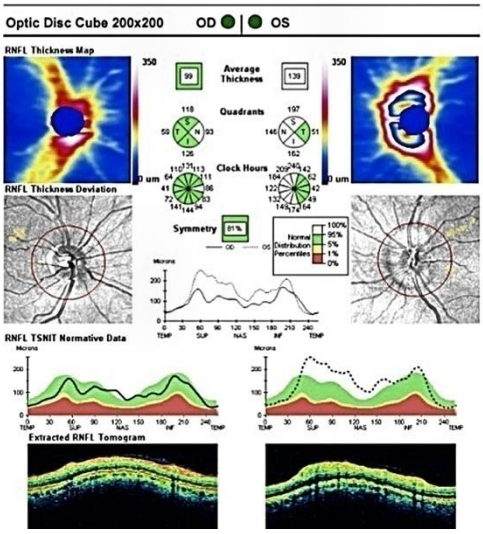

Fig. 4. OCT –RNFL normal in the RE and thickened in the LE

The Humphrey visual field analyzer full field 120 points showed a central scotoma (fig. 5) and Roth 28 Hue test revealed dyschromatopsia in both axes, blue/yellow and red/green (fig. 6).

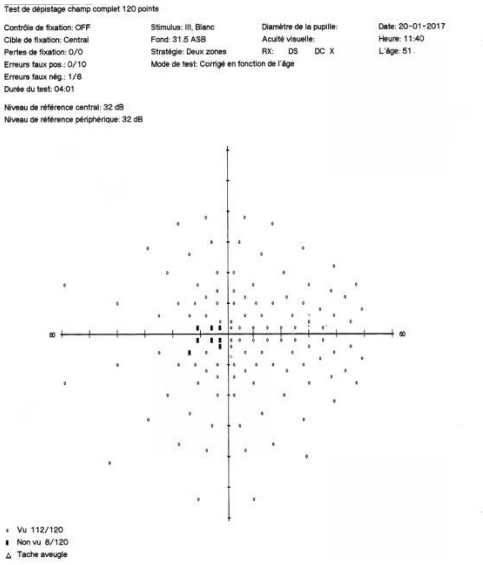

Fig. 5. Visual field LE central scotoma

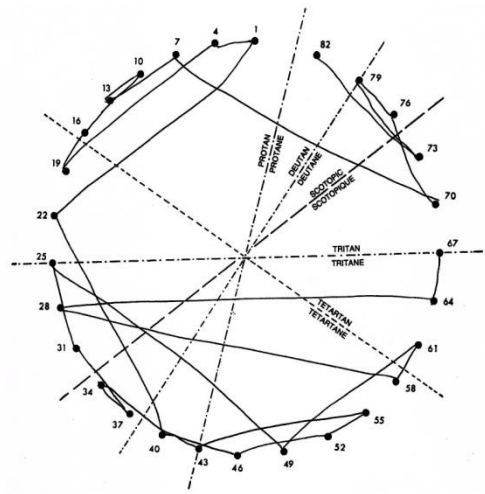

Fig. 6. Roth 28 Hue Test dyschromatopsia

Our first diagnosis was of LE optic neuritis of unknown cause. Initial differential diagnosis included infectious causes (bacterial-Lyme disease, syphilis, tuberculosis, toxoplasmosis; viral - influenza, herpes simplex, herpes zoster, cytomegalovirus), demyelinating causes such as MS, autoimmune diseases (sarcoidosis, systemic lupus erythematosus), compressive or infiltrative diseases.

First, we wanted to exclude a neurosurgical problem, elevated intracranial pressure, as the cause of optic nerve swelling, so we used magnetic resonance imaging (MRI). The MRI revealed unilateral optic nerve swelling, with high T2 signal and contrast enhancement, with no other pathological findings such as expansive intracranial mass or demyelinating MS lesions (fig. 7).

Following exclusion of elevated intracranial pressure, we carried out complete blood tests, including complete blood count, specific antibodies for autoimmune and infectious diseases. The blood count revealed lymphocytosis (55%) and neutropenia (37%). A rapid influenza diagnostic

test was positive for type A influenza. Chest radiography showed no pathological features. Antibodies against Borrelia, Toxoplasma, Treponema pallidum (TPHA), Bartonella henselae, Rickettsia were absent. Tuberculin skin test was negative. As for viruses, we found borderline IgM antibody against herpes simplex virus and positive varicella zoster virus (1.505 mIU/mL) and cytomegalovirus IgG antibodies. The angiotensin converting enzyme was negative (35 U/L), the rheumatoid factor IgM borderline (22 UI/mL), and the antinuclear antibodies (ANA), anti-DNA antibodies and perinuclear anti-neutrophil cytoplasmic antibodies (pANCA) were negative.

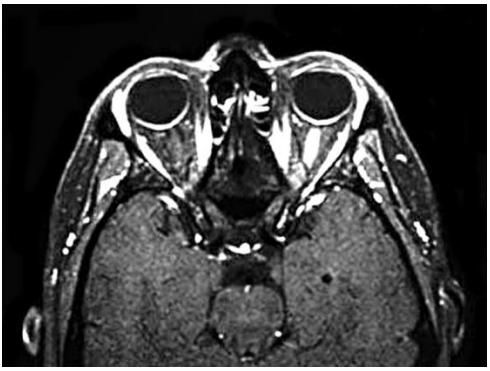

Fig. 7. MRI - LE optic nerve contrast enhancement

Based on medical history, fundus appearance, OCT, VF and laboratory investigations (MRI, blood tests), the diagnosis of LE viral optic neuritis associated with influenza was made. High dose corticotherapy with methylprednisolone (1 g/day for 3 days) was initiated and then decreased to 1mg/body weight. An oral antiviral agent, oseltamivir phosphate 75 mg, was administered twice a day for 5 days. One week later, the disc edema and the hemorrhage were resolved, with slow VA improvement over the first month. Two months later, the VA in the LE was 8/10.

DISCUSSION

Optic nerve involvement with variable visual impairment has been associated with a wide variety of infectious disorders (5). The pathogenesis of infectious optic neuropathies remains speculative. Direct involvement of the optic nerve by a pathogen and indirect involvement with inflammatory, degenerative or vascular mechanisms might contribute to the development of optic nerve involvement (6). Appropriate clinical diagnosis and laboratory work-up of a patient with infectious optic neuropathy are based on history, systemic symptoms and signs, epidemiological data. A few cases of optic neuritis in the setting of influenza infection have been reported. The visual outcome was good after corticosteroid therapy. Neuroretinitis and neuromyelitis optica with a self-limited course were also reported (7). However, there are few reports on ocular complications of influenza A infection. These reports described symptoms such as impaired ocular movement, keratitis, macular lesion, angiitis (8). More often, optic neuritis associated with influenza occurs in children and affects both eyes. We described the case of a 51-year-old woman diagnosed with optic neuritis associated with influenza, which responded well to pulse steroid therapy for 3 days, with smooth recovery from blurred vision and ocular inflammation. Lai reported the first case of acute anterior uveitis and optic neuritis after influenza A infection in a 11-year-old boy. This patient achieved VA improvement with high-dose intravenous pulse steroid therapy for 3 days (9). Nakagawa reported a rare case of acute

anterior uveitis and optic neuritis associated with influenza A infection, which also responded well to corticosteroid therapy (10). Optical coherence tomography suggests involvement of axons (gray matter) in addition to myelin sheath (white matter) in this process. Recent studies have shown that OCT-measured RNFL values may represent a marker for axonal damage in the anterior visual pathway of optic neuritis (11).

CONCLUSIONS

Optic neuritis has been associated with a wide variety of infectious disorders. It is very important to make a thorough examination of a patient with optic nerve involvement to establish the correct diagnosis.

We described a rare case of unilateral optic neuritis associated with influenza A infection in an adult patient. This case calls our attention to the unusual association between systemic infection and optic nerve inflammation. Despite the important decrease in visual acuity at presentation and the optic disc edema, the patient responded well to corticosteroid therapy, with almost full recovery of the visual acuity. Studying the literature, we found very few reports on ocular complications of influenza A infection in adults.

TAKOTSUBO CARDIOMYOPATHY (Abstract): Takotsubo cardiomyopathy or “heart broken syndrome” or transient apical ballooning syndrome is an increasingly reported syndrome characterized by the fact that most patients are women aged over 65 years. The most common electrocardiographic changes are ST-segment elevation and negative T waves in precordial leads. Symptoms at onset are similar to those of acute myocardial infarction; the ventricular dysfunction is shaped like a *takotsubo* (a Japanese pot for fishing octopus), echocardiography and ventriculography show akinesia, hipokinesia or diskinesia(ballooning) of apical segments of left ventricle and hyperkinesia of the basal; the coronary arteries are normal angiographic; the dysfunction improves rapidly within a few weeks. Its origins are unclear, there are several pathophysiological theories, most sustained is a myocardial stunning secondary catecholamine-induced excess of intense physical or mental stress. There is no clear standard of treatment. In cases evolving with hemodynamic instability the use of beta agonist agents must be avoided, aortic balloon counterpulsation is preferable. The patient prognosis is usually good, reaching maximum mortality of 8%. In rare situations were reported complications such as acute pulmonary oedema, cardiogenic shock, acute mitral regurgitation, potentially fatal arrythmias ventricular fibrillation or torsades de pointes. In Cardiology Clinic of Cardiovascular Diseases Institute “Prof. Dr. George I.M. Georgescu” Iasi were hospitalized 4 cases with Takotsubo cardiomyopathy from 2008 to 2011. Their features are presented in this paper. The difference of prognosis and treatment between Takotsubo cardiomyopathy and acute myocardial infarction require an accurate diagnosis, the clinical hypothesis result only after knowledge the clinical and paraclinical peculiarities of this pathological entity. **Key words:** TAKOTSUBO, CARDIOMYOPATHY, APICAL BALLOONING SYNDROME.

Cardiomiopatia Takotsubo este un sindrom caracterizat prin manifestări clinice compatibile cu cele din infarctul miocardic acut(IMA), supradenivelare de segment ST şi unde T negative în derivațiile precordiale, creştere uşoară sau moderată a enzimelor de citoliză miocardică, tulburări tipice de kinetică regională de ventricul stâng (VS), complet reversibile, în prezența unor artere coronare normale angiografic sau fără leziuni semnificative.

În paralel cu datele teoretice vom prezenta particularitățile a patru cazuri de cardiomiopatie Takotsubo, diagnosticate în Institutul de Boli Cardiovasculare Iaşi, în perioada 2008 – 2011.

ETIOLOGIE

Cauza acestui sindrom rămâne necunoscută (1). S-a constatat că afectează predominant femeile în postmenopauză (apare într-un procent de 70 – 80% la femei de peste 65 ani), cel mai frecvent după un stres emoţional sau fizic (1, 2). Factorul stresor anterior este o caracteristică importantă, în literatură citându-se foarte rare cazuri când acesta nu a putut fi anamnestic decelat.

În clinica noastră, toate cele 4 cazuri de cardiomiopatie Takotsubo au fost femei, anamneza punând în evidenţă un stres psihic intens anterior declanşării simptomatologiei.

EPIDEMIOLOGIE

Datorită caracteristicelor sale, în camera de gardă este adesea confundat cu un sindrom coronarian acut prin obstrucţie coronariană, motiv pentru care este dificil de estimat prevalenţa reală a acestei afecţiuni. Datele din literatură indică o prevalenţă de 2% din totalul cazurilor de sindroame coronariene acute, cu o creştere în ultimii ani probabil prin scăderea cazurilor de diagnostic fals negativ (2).

PATOGENIE

S-au elaborat mai multe teorii cu privire la fiziopatologia acestui sindrom, fără a exista un concept unitar. Cea mai susţinută teorie este cea a unui *stunning* miocardic indus de descărcarea în exces de catecolamine, consecinţă a unui stres puternic, psihic sau fizic. Catecolaminele, în cantitate crescută, pot determina prin efect direct injurie miocardică (toxicitate catecolaminică). Modificările histologice tipice de toxicitate catecolaminică sunt observate în cardiomiopatia Takotsubo precum şi în alte condiţii clinice asociate cu producţie crescută de catecolamine - feocromocitom, hemoragie subarahnoidiană. De remarcat faptul că anomaliile de kinetică întâlnite în cardiomiopatia Takotsubo nu sunt similare cu cele din hemoragia subarahnoidiană sau intracraniană când sunt afectate segmentele bazale ale VS (deşi conform acestui concept au acelaşi mecanism fiziopatologic) (1).

Alte teorii propuse pentru fiziopatologia acestui sindrom sunt cea a unui spasm miocardic multivascular (nu a fost demonstrat decât la un număr mic de pacienţi) şi cea a unei disfuncţii endoteliale generalizate la nivelul microcirculaţiei (este neclar dacă reprezintă mecanismul patogenic primar sau este un fenomen secundar; în plus, cauza acestei disfuncţii endoteliale rămâne necunoscută) (1).

CLINIC

Cele mai frecvente simptome de debut sunt durerea toracică anterioară similară celei din IMA, dispnee şi uneori sincopă(3). Au fost semnalate cazuri cu degradare hemodinamică – edem pulmonar acut, şoc cardiogen(4). Au fost citate aritmii cu potenţial letal – fibrilaţie ventriculară, torsada vârfurilor (1,2,5,6).

Un caz de cardiomiopatie Takotsubo diagnosticat în clinica noastră s-a manifestat prin şoc cardiogen, ceea ce a impus măsuri suplimentare şi speciale de tratament (inclusiv contrapulsaţie aortică cu balon). Nu s-au înregistrat aritmii maligne în nici unul din cele 4 cazuri, dar la pacienta cu şoc cardiogen s-a iniţiat încărcarea cu amiodaronă în contextul instalării fibrilaţiei atriale.

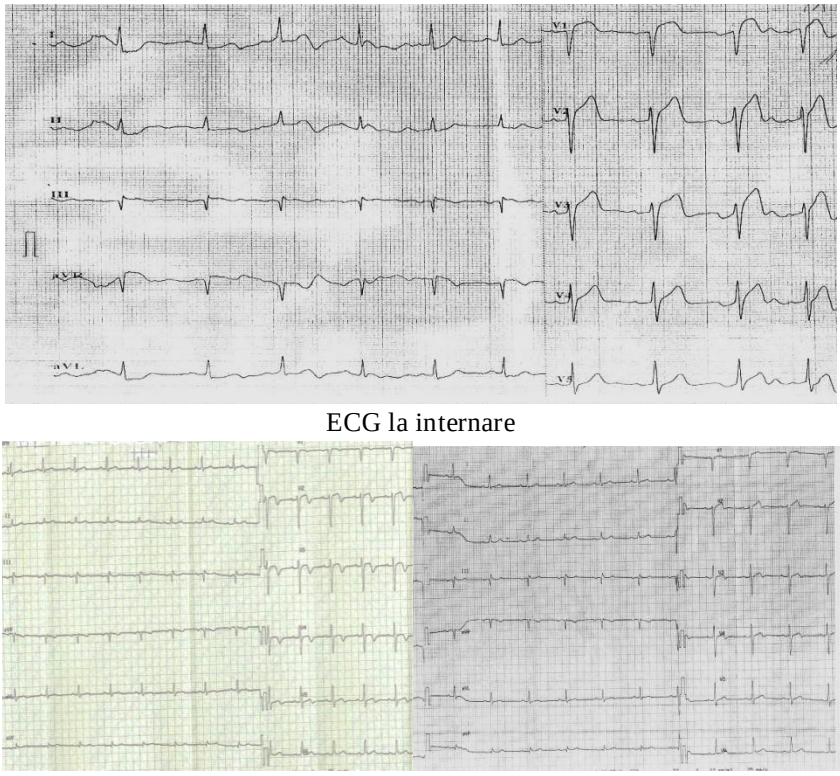
ELECTROCARDIOGRAFIC

Cele mai frecvente modificări sunt supradenivelarea de segment ST şi unde T negative în derivaţiile precordiale, ce au fost descrise de unii autori ca evoluând în stadii succesive (1,5,7).

În evoluţie apar unde T negative, adânci, largi, cu alungirea intervalului QT

– anomalie ce poate explica apariția uneori a tulburărilor de ritm maligne. Într-o proporție mai scăzută pot apare şi unde Q patologice (2,8).

Modificările electrice înregistrate în cele patru cazuri din clinica noastră sunt comparabile cu cele descrise în literatura de specialitate (fig. 1).



ECG la internare

ECG în ziua a treia de evoluție ECG la externare

Fig. 1. Evoluția modificărilor electrice într-un caz de Cardiomiopatie Takotsubo spitalizat în IBCV Iaşi

BIOCHIMIC

Enzimele de citoliză miocardică sunt uşor - moderat crescute, dar pot fi şi în limite normale după unii autori; de asemenea, s-au descris concentrații serice crescute de BNP la pacienții cu cardiomiopatie Takotsubo; valori serice scăzute ale NT pro-BNP s-au corelat cu evoluția favorabilă a acestui sindrom (1).

În clinica noastră, s-a determinat CK-MB, valorile maxim înregistrate fiind modeste şi în concordanță, de asemenea, cu datele din literatură (33 U/L - 68U/L).

ECOCARDIOGRAFIC

În secțiunea apicală a 4 camere se evidențiază modificările tipice de kinetică regională ale cardiomiopatiei Takotsubo: akinezia, hipokinezia sau diskinezia segmentelor apicale ale ventriculului stâng şi hiperkinezia celor bazale, aspect morfologic care a dus la denumirea de "takotsubo". Fracția de ejecție(FE) a VS este deprimată, cu valori ce variază între 20% - 49%(2). În

foarte puține cazuri s-au descris trombi apicali (9,10). În unele situații, în faza acută, s-a evidențiat obstrucție la nivelul tractului de ejecție a VS, după unii autori cu un gradient maxim de până la 60 mmHg. De asemenea, a fost observată balonizarea medioventriculară ce separă segmentele apicale de cele bazale (11,12) sau insuficiența mitrală acută (1,13).

Au fost raportate cazuri care au evoluat cu implicarea ventriculului drept(VD), situații în care s-a semnalat o deprimare mai accentuată a FE a VS. Segmentele cele mai frecvent afectate ale VD au fost: lateroapical, anterolateral şi cel inferior. Reacția pleurală a fost descrisă ca fiind adesea asociată acestor cazuri (14). Au fost raportate cazuri de Takotsubo inversat, caracterizate printr-un stunning al segmentelor bazale şi hiperkinezie a celor apicale (15). Tulburările de kinetică descrise în cardiomiopatia Takotsubo sunt complet reversibile într-un interval de timp de zile – săptămâni, ceea ce constituie una dintre cele mai importante caracteristici ale acestui sindrom.

CORONAROGRAFIA ŞI VENTRICULOGRAFIA

În toate cazurile raportate, coronarografia a exclus prezența leziunilor coronariene semnificative, caracteristică importantă a acestui sindrom. Ventriculografia evidențiază anomaliile de kinetică regională (fig. 2).

Fig.2. Coronarografie, ventriculografie (efectuată de I. Nedelciuc) şi secțiune ecocardiografică în sistolă la o pacientă spitalizată în IBCV Iaşi pentru Cardiomiopatie Takotsubo

Într-unul din cazurile din clinica noastră, suplimentar față de tulburările tipice de kinetică regională, s-a obiectivat insuficiența mitrală acută prin ischemia muşchiului papilar, ceea ce explică şi starea clinică gravă de la internare (şoc cardiogen) (fig. 2).

Pacientele diagnosticate cu cardiomiopatie Takotsubo în clinica noastră nu au prezentat leziuni coronariene semnificative, criteriu fundamental pentru susținerea diagnosticului (fig. 2).

ALTE INVESTIGAȚII

Rezonanța magnetică nucleară oferă informații privind morfologia şi funcția VS şi exclude infarctul miocardic sau existența unui proces inflamator. În numeroase cazuri s-a evidențiat un defect de perfuzie în regiunile apicale în timpul fazei acute, în pofida absenței leziunilor coronariene semnificative, modificări ce se ameliorează progresiv în timpul fazei de recuperare. S-au realizat biopsii endomiocardice atât de la nivelul VS, cât şi a VD ce nu au evidențiat semne de miocardită (1).

ALTE INVESTIGAȚII

Rezonanța magnetică nucleară oferă informații privind morfologia şi funcția VS şi exclude infarctul miocardic sau existența unui proces inflamator. În numeroase cazuri s-a evidențiat un defect de perfuzie în regiunile apicale în timpul fazei acute, în pofida absenței leziunilor coronariene semnificative, modificări ce se ameliorează progresiv în timpul fazei de recuperare. S-au realizat biopsii endomiocardice atât de la nivelul VS, cât şi a VD ce nu au evidențiat semne de miocardită (1).

TRATAMENT

Nu există o standardizare clară a tratamentului. Se consideră totuşi necesar abordarea inițială a acestor pacienți similar celor cu IMA, până la obținerea unui diagnostic diferențial invaziv. În cazurile ce evoluează cu instabilitate hemodinamică, trebuie evitată utilizarea de agenți ß-agonişti, în aceste situații fiind preferabil suportul mecanic – balon de contrapulsație aortică. În clinica noastră acesta a fost montat la pacienta care a evoluat cu şoc cardiogen.

Studiile efectuate pe animale au arătat că evoluția a fost îmbunătățită de administrarea de agenți ß-blocanți care ar trebui utilizați atât în faza acută, cât şi cea cronică în vederea prevenției recurenței, care poate apare până la 8% din cazuri (1).

Având în vedere cazurile citate în literatură care au evoluat cu formare de trombi în VS, unii autori consideră prudent instituirea unui tratament anticoagulant cu heparină până la recuperarea funcției sistolice a VS. Dintre agenții terapeutici utilizați în cazurile citate în literatură mai fac parte inhibitorii enzimei de conversie a angiotensinei şi antiagregantele plachetare.

PROGNOSTIC

Prognosticul pacienților cu cardiomiopatie Takotsubo este favorabil, rata mortalității intraspitaliceşti raportată fiind cuprinsă între 0–8% (1). Simptomatologia, modificările electrocardiografice, enzimatice şi eco-cardiografice dispar în majoritatea cazurilor într-un interval de timp variabil (zile – săptămâni) (1).

Evoluția intraspitalicească a cazurilor din clinica noastră a fost favorabilă. Cel mai precoce, tulburările de kinetică au dispărut într-unul din cazuri după 20 ore de evoluție. Pacienta cea mai gravă, care a prezentat inițial şoc cardiogen şi insuficiență mitrală acută severă, a avut o evoluție lent favorabilă, cu dispariția tulburărilor de

kinetică segmentară şi reducerea regurgitării mitrale până la gradul I, după trei luni de tratament.

CONCLUZII

Deşi relativ rară**,** cardiomiopatia Takotsubo este o afecțiune cu care trebuie făcut diagnosticul diferențial al unui infarct miocardic acut în anumite situații particulare. Diferențele terapeutice şi prognostice dintre aceasta şi IMA, fac necesar un diagnostic corect cât mai precoce, ipoteza clinică de boală Takotsubo putând rezulta doar în urma cunoaşterii şi aprofundării particularităților clinice şi paraclinice a acestei entități patogenice.

Facultatea de Medicină
Spitalul Clinic de Urgenţă „Sf. Spiridon” Iaşi
Clinica a III-a Medicală Cardiologică

MALIGNANT HYDATID DISEASE – CASE PRESENTATION (Abstract): We report the case of a 79-year-old woman admitted for sepsis from a hepatic hydatid cyst with multiple disseminations diagnosed one month earlier who refused the surgical treatment. Her family history was irrelevant with regard to the circumstances leading to *Taenia Echinococcus* infestation, and given her poor health status and absence of previous medical documents no useful information was obtained from her medical history. The patient also presented chronic ischemic heart disease and anemia secondary to a bleeding duodenal ulcer, found at necropsy, which worsened the already unfavorable course by the acute hepatic and renal failure secondary to toxic and septic shock. Despite the complex treatment, death occurred 6 days later, following a second episode of upper digestive hemorrhage. Particular to this case is the absence in patient’s history of the anaphylactic/allergic reactions suggestive of hepatic hydatid cyst dissemination. **Key words:** DISEMINATED HEPATIC CYST, MALIGNANT HYDATID DISEASE, TAENIA ECHINOCOCCUS.

Maladia hidatică este determinată de agentul patogen Taenia echinococcus care poate infesta organismul uman la orice vârstă exprimându-se prin suferința organului afectat atunci când determină fenomene compresive sau prin complicații. Având în vedere posibilitatea infestării la nivelul oricărui organ cu caracter primar sau secundar precum şi severitatea evolutivă în absența tratamentului adecvat această boală a fost cunoscută şi sub denumirea de “hidatidoză malignă”. Prezentarea cazului urmăre şte caracterul imprevizibil şi incurabil al acestei boli ajunsă în stadiul de complicații.

PREZENTAREA CAZULUI

D.M , 79 ani, sex feminin din localitatea Ia şi, jud. Ia şi, a fost internată în clinică pentru dureri abdominale difuze, astenie fizica marcată, stare septică, simptomatologie progresiv agravată în ultima lună. Dintre antecedentele personale patologice s-a remarcat diagnosticarea cu o luna anterior la vârsta de 79 ani a cardiomiopatiei ischemice complicate cu fibrilație atrială permanentă şi insuficiență cardiacă cronică globală ocazie cu care s-a menționat prezenta unui chist hidatic hepatic complicat, pentru care s-a recomandat tratament chirurgical refuzat de pacientă şi de familie. Din anamneza efectuată cu ajutorul familiei nu s-a putut semnala în antecedente existența unor circumstanțe care să explice infestarea cu *T. echinococcus* iar condițiile de viață şi muncă nu au obiectivat circumstanțe particulare cu implicații patologice.

Istoricul pacientei nu s-a putut face corect, anamneza fiind dificilă atât prin starea generală influențată cât și prin lipsa documentelor medicale antecedente. Cu o lună anterior a fost internată într-o clinică medicală pentru investigarea simptomelor cardiovasculare cronice, concomitent diagnosticându-se chist hidatic hepatic cu posibilă diseminare peritoneală precum și un sindrom anemic de etiologie neprecizată. Sub medicația necesară patologiei cardiace, la domiciliu, starea generală a pacientei s-a degradat rapid și progresiv, apărând dureri abdominale difuze, anorexie și astenie fizică.

Examenul clinic a relevat tegumente și mucoase palide, afebrilitate, semne de deshidratare (limba prăjită, pliu cutanat persistent), elemente de decompensare cardiacă globală exprimată prin edeme membre inferioare, raluri crepitante bazal bilateral, jugulare turgide gr. 3, TA la internare 100/60 mmHg, zgomote cardiace tahiaritmice 100/min, hepatomegalie din sp.VI medioclavicular drept la 10 cm sub rebordul costal cu contur neregulat, dura, dureroasă la palpare superficială, cu apărare musculară la palparea profundă, formațiuni tumorale multiple, de dimensiuni diferite, palpabile pe suprafata abdominală, oligoanurie (aprox. 400ml/24h), confuzie.

Datele de laborator au arătat sindrom de retenție azotată cu accentuare progresivă - creatinina de la 2,03 mg/dl la internare la 3,20 mg/dl, ureea de la 159 mg/dl la 308 mg/dl in urmatoarele 5 zile, anemie hipocromă microcitară feriprivă cu evoluție de la 10 g/dl la 8,4 g/dl, fier seric 12 µg/dl, sindrom inflamator nespecific (leucocitoză - de la 18300/mm^3 la 22800/mm^3 cu neutrofilie 85% și eozinofilie 7%, VSH crescut - 99mm/1h, 131mm/2h), hipopotasemie – 2,8 mEq/l (la internare, ulterior corectată).

Pe EKG s-a obiectivat fibrilație atrială cu frecvența ventriculară medie de 80/min, elemente de impregnare digitalică.

Radiografia toracică - ICT=0,58, cord cu dimensiuni crescute, aorta ateromatoasă, desen pulmonar accentuat. Ecocardiografic - aspect de cardiomiopatie ischemică și hipertensivă, calcificări de valvă mitrală și aortică cu regurgitare aortică moderată, regurgitare mitrală severă, regurgitare tricuspidiană severă, revărsat lichidian pericardic în cantitate moderată.

La ecografia abdominală s-au evidențiat chist hidatic hepatic în segmentul VI cu dimensiuni de 95/67/76 mm (fig. 1), un alt chist hidatic în segmentul III de 90/112/56 mm cu mici vezicule fiice în periferie cu tendința la decolarea membranei (fig. 2) și un alt chist hidatic cu vezicule fiice localizat subhepatic în dreptul lobului stâng hepatic cu dimensiuni de 53/34/52 mm (fig. 3); rinichi drept si stang normali, splină normală.

Datele obținute clinic și paraclinic au pus în discuție prezența unei hidatidoze complicate cu supurație și diseminări multiple, cu elemente de insuficiență hepatică și renală acută secundare șocului toxicoseptic, fără a se putea explica tipul anemiei (în aceste circumstanțe – de tip inflamator)

Evoluția a fost nefavorabilă în ciuda tratamentului complex administrat și în a 5-a zi de la internare pacienta a prezentat un episod de melenă pentru care s-a instituit tratament medicamentos, starea generală gravă nepermițând endoscopia digestivă superioară. Decesul a survenit in a 6-a zi de evoluție după al doilea episod de hemoragie digestivă superioară (hematemeza), prin stop cardiorespirator ireversibil la manevrele de resuscitare. Anamneza antecedentelor personale patologice, reluata cu ajutorul familiei, nu a semnalat prezența unor leziuni digestive cunoscute cu potențial hemoragic.

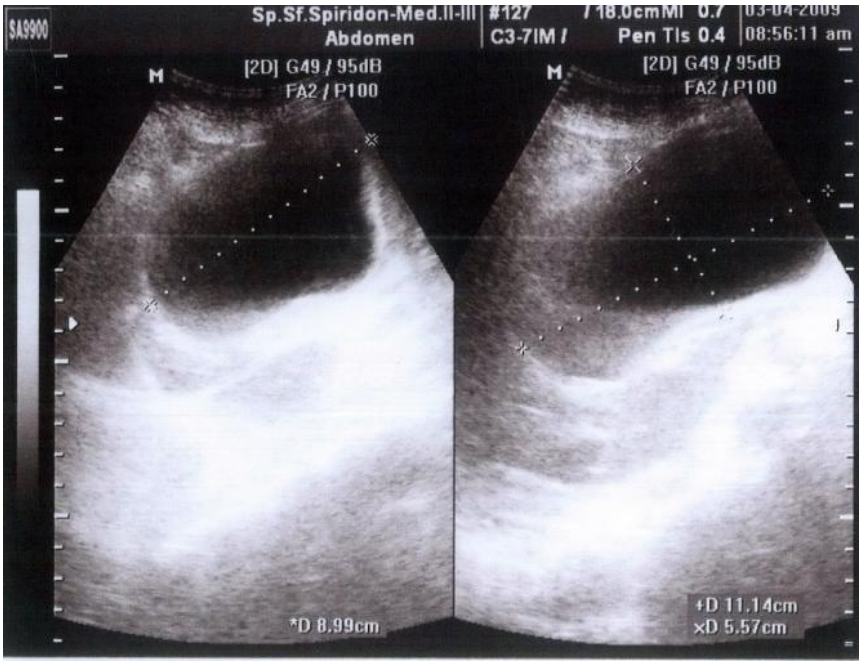

Fig. 1. Chist hidatic hepatic

Fig. 2. Chist hidatic cu decolarea membranei

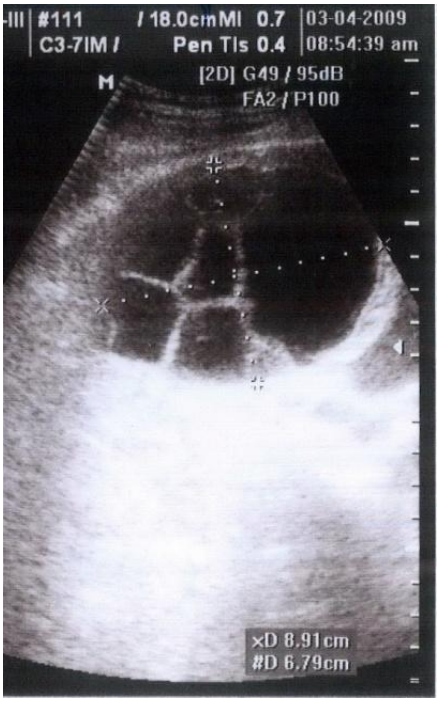

Fig. 3. Chist hidatic cu vezicule fiice

Examenul necroptic efectuat a arătat multiple chisturi hidatice hepatice (lob stâng şi drept), peritoneul aderent şi calcificat la marginea anterioară a ficatului, aderenţe strânse ale unghiului hepatic al colonului la unul din chisturile hidatice din lobul hepatic drept şi inflamaţie purulentă de tip flegmonos subhepatic şi perirenal drept, ulcer duodenal hemoragic (2,5/1,5 cm) însoţit de multiple ulceraţii hemoragice de vecinătate, tub digestiv cu conţinut hemoragic parţial digerat, cardiomegalie cu hipertrofie ventriculară stîngă concentrică si dilatarea cavităţilor drepte, aterosclerozã generalizată cu plăci calcificate aortice, unele ramolite, stază şi edem pulmonar.

DISCUŢII

Boala chistică hidatică se datorează în special *Echinococcus granulosus*. Infestarea cu *E. vogeli* este foarte rară şi este raportată în special în zonele sudice ale Americii de Sud (3). Infestarea cu *E. granulosus* este endemică în regiunile crescătoare de oi şi vite din Orientul Mijlociu, ţările din bazinul Mediteranei, Europa Centrală şi de Est, America de Sud, Australia, Noua Zeelandă şi Africa de Sud (1, 2, 3).

La om hidatidoza este cel mai frecvent hepatică (55-70%), apoi pulmonară (18-35%) iar aceste două organe pot fi afectate simultan în 5-13% din cazuri (4, 5). Incidenţa echinococcozei cistice în regiunile endemice este de 1-220 cazuri la 100.000 locuitori, pe când incidenţa echinococcozei alveolare este de 0,03-1,2 cazuri la 100.000 locuitori (3).

La fel ca şi în alte infecţii date de cestode, speciile de echinococcus prezintă atât gazde definitive cât şi gazde intermediare. Gazdele definitive sunt câinii care elimină ouăle în materiile fecale. Atunci cînd gazdele intermediare – omul, bovinele, oile, caprele, caii (pentru *E. granulosus*) şoarecii şi alte rozătoare (pentru *E. multilocularis*) – ingeră ouăle, în organismul acestor gazde se dezvoltă chisturi. Atunci când un câine ingeră carne de vită sau de oaie conţinând chisturi, ciclul biologic e finalizat (6).

Manifestările clinice ale bolii depind de mărimea şi localizarea chisturilor. Majoritatea pacienţilor rămân asimptomatici până la vârste înaintate cum este şi cazul pacientei noastre. Chisturile produc disfuncţia organelor afectate inclusiv obstrucţie biliară, ciroză, obstrucţie bronşică, insuficienţă renală, hipertensiune intracraniană şi hidrocefalie. Pacienţii simptomatici cu hidatidoză hepatică prezintă de cele mai multe ori dureri abdominale sau o formaţiune palpabilă în cadranul superior drept. Compresia tractului biliar sau scurgerea lichidului din chist în arborele biliar poate mima litiaza biliară recurentă, obstrucţia biliară putând avea ca rezultat apariţia icterului. Ruptura sau scurgerea episodică dintr-un chist hidatic poate produce febră, prurit, urticarie, eozinofilie sau un episod anafilactic fatal.

Echinococcoza peritoneală poate apare în 2 circumstanţe (6): primitivă – prin migrarea unui chist hidatic hepatic în cavitatea peritoneală, localizarea fiind de obicei declivă (fosele iliace), uniloculară şi pe suprafaţa ficatului se pot detecta alte chisturi sau cicatrici; secundară – postoperator sau posttraumatic de la nivelul unui chist hidatic hepatic, localizarea fiind multiplă în toată cavitatea peritoneală.

Diagnosticul imagistic este important pentru detectarea şi evaluarea chisturilor hidatice. Radiografiile simple detectează chisturile pulmonare precum şi chisturile cu perete calcificat de exemplu de la nivel hepatic. Examenul ecografic şi computer tomografic pun în evidenţă leziunile primare

precum şi veziculele fiice (7, 17, 18). Examinarea prin rezonanță magnetică nucleară este superioară tomografiei computerizate pentru evaluarea recurențelor, leziunilor reziduale postchirurgicale precum şi pentru evidențierea unor determinări extrahepatice (19). Diagnosticul specific trebuie realizat prin examinarea lichidului aspirat în vederea evidențierii cârligelor scolecşilor, dar aspirația în scop diagnostic nu este recomandată, în mod normal, datorită riscului scurgerii lichidului hidatic şi producerii unor reacții anafilactice sau diseminării infecției. Analizele serologice pot fi utile (8), cu toate că un rezultat negativ nu exclude diagnosticul echinococcozei. Comparativ cu chisturile pulmonare, chisturile hepatice induc mult mai probabil răspunsuri imune umorale , dar pâna la 50% dintre indivizii afectați pot avea analize serologice negative (6).

Tratamentul constă în ablația chirurgicală (9, 10, 11, 12, 13, 21). De asemenea, administrarea pre- şi post - operator timp de o lună de Albendazol şi 2 săptămâni de Praziquantel ar trebui efectuată pentru sterilizarea chistului, scăderea tensiunii intrachistice, scăderea riscului de şoc anafilactic şi reducerea recăderilor postoperatorii (22). Studii recente afirmă necesitatea continuării tratamentului timp de 2 ani, fără efecte secundare semnificative (19, 20).

La cazul prezentat se remarcă descoperirea întâmplătoare a chistului hidatic hepatic la vârsta de 79 ani cu ocazia investigațiilor patologiei cardiovasculare. La această pacientă a coexistat un sindrom anemic care ar fi putut preta la probleme de diagnostic diferențial a formațiunii chistice intrahepatice precum şi alterarea organică funcțională complexă care a creat particularități de exprimare ale maladiei dar şi evoluția spre depreciere rapidă. În experiența clinică mondială sunt rar semnalate complicații asociate de tip suprainfectare a formațiunii chistice la nivelul unui organ coexistând cu diseminări la nivelul altor organe, ceea ce presupune evoluția fie primară a unei hidatidoze multiple de organe, fie fisurarea leziunii primare cu luni/ani anterior şi exprimarea clinică a complicațiilor infecțioase recent produse (6).

În aceste circumstanțe considerăm ca fiind o particularitate semnificativă absența reacțiilor alergice/anafilactice în antecedentele pacientei care ar fi putut exprima diseminarea unui chist hidatic hepatic fisurat. În literatură se semnalează că asemenea incidente sunt marcate de suprainfecția chistului şi/sau obstrucția tractului biliar sau arborelui bron şic având drept consecințe pneumonia, revărsatul pleural, pneumotoraxul, echinococcoza secundară în cavitatea pleurala, peritoneală sau pericardică (23).

Deşi pacienta şi familia sa au refuzat tratamentul chirurgical propus într-o internare precedentă, la descoperirea formațiunii chistice hepatice, evoluția ulterioară a cazului şi rezultatul anatomo-patologic necroptic susțin imposibilitatea rezolvării acestei patologii complexe în ciuda tratamentului recomandat în literatură (tratamentul chirurgical asociat cu chimioterapie specifica). Aceste cazuri, deşi rare, reprezintă un semnal de alarmă asupra subevaluării diagnostice mai ales în circumstanțele unui mod de viață precar igieno-sanitar care poate determina risc crescut de infestare. Simptomele clinice de tip imunoalergic, explorările ecografice abdominale efectuate cu atenție ar putea fi metode de diagnostic şi tratament în timp util. Abordarea diagnostică optimă este la nivel de medicină de famile deoarece pot fi apreciate cel mai corect condițiile de mediu ale pacienților şi verigile de legatură din etapele lanțului infestării.

ASPECTS OF THE ANTIMICROBIAL RESISTENCE PROFILE IN INFECTIONS WITH ESCHERICHIA COLI AND KLEBSIELLA PNEUMONIAE IN DIABETIC PATIENTS (Abstract): Infections in diabetic patient remains an important cause of morbidity and mortality, triggering and maintaining a prolonged metabolic imbalance. Emergence of extented spectrum beta-lactmase (ESBL) in *Escherichia coli* and *Klebsiella pneumoniae* is a major concern, because of the atypical manner infection acts in this group of imunodepressed patients and also for the limited therapeutic solutions. For this reason we have evaluated the profile of antimicrobial resistance of these pathogens in both diabetic and non diabetic patients**. Material and method:** The aim of this study was to evaluate, in a retrospective case control study, the antibiotic susceptibility pattern in isolates of *E. coli* and *Klebsiella spp*. from different biological products in 49 diabetics and 150 non-diabetics admitted in The Clinical Hospital of Infectious Diseases Iași over a period of two years. **Results:** Most of strains of *E. coli* and *Klebsiella spp*. ESBL positive were found in uroculture. Significant differences in *E. coli* resistance rate between diabetics and non-diabetics were noted for amoxicillin-clavulanic acid and ciprofloxacin (31,4% vs.13,98%, p=0,04, respectively 52,9% vs. 24,46%, p=0,004). More isolates of ESBL positive *K. pneumoniae* were found in diabetic patients (50% vs. 24%). Ciprofloxacin resistance of *K. pneumoniae* was significantly higher in diabetics (75% vs 39%; p=0,05). There was no resistance in *E. coli* and *K. pneumoniae* isolates to imipenem in the diabetic group. **Conclusions:** The high resistance rate to quinolones and 3rd generation cefalosporins limits their use for the treatment of *Escherichia coli* and *K. pneumoniae* infections. Other alternatives for empiric therapy in community and nosocomial-acquired infections in diabetic patient remains carbapenems, aminoglycosides and colimycin. **Key words:** GRAM NEGATIVE INFECTIONS, DIABETIC INFECTION, ESBL, *KLEBSIELLA SPP., ESCHERICHIA COLI.*

Infecțiile cu bacili Gram negativ (BGN) la bolnavul diabetic constituie o cauză de morbiditate și mortalitate ridicată, fiind responsabile de declanșarea și menținerea

unui dezechilibru metabolic prelungit. Pacienţii cu diabet par a avea un risc particular crescut pentru infecţii cum ar fi otita externă invazivă, mucormicoza rinocerebrală, infecţii emfizematoase ale veziculei biliare, rinichilor şi vezicii urinare, cu o evoluţie şi un prognostic adesea nefavorabil.

Infecţiile formatoare de gaz de la nivel parenchimului renal, ureterului sau vezicii urinare survin în peste 90% din cazuri la pacienţii diabetici, patogeneza acestei boli fiind probabil legată de abilitatea unor microorganisme cum ar fi *E. coli* sau *K. pneumoniae* de a utiliza glucoza cu formare ulterioară de dioxid de carbon şi hidrogen. Mortalitatea globală în aceste situaţii ajunge la 18% (7).

K. pneumoniae este printre cele mai frecvente microorganisme întâlnite la nivel mondial, fiind implicată atât în infecţii nosocomiale (pneumonie, infecţii ale tractului urinar, infecţii intraabdominale), cât şi în infecţii comunitare. Pe lângă tabloul clinic dramatic al pneumoniei comunitare cu *Klebsiella* descris în studii din anii 1920-1960, cu o incidenţă în descreştere în ultima decadă (mai puţin de 1% de cazuri spitalizate în America de Nord), noi entităţi clinice ale infecţiei comunitare cu *K. pneumoniae* au fost obiectivate de diferiţi autori, în special în Asia (1, 2). Peste 900 de pacienţi cu abces hepatic cu *Klebsiella* au fost raportaţi în Taiwan în ultimii 10 ani, 70% dintre aceştia având diabet zaharat. În contrast, doar 23 de pacienţi au fost raportaţi cu aceeaşi condiţie în regiuni nonasiatice (3). Infecţiile cu tulpini de *E.coli* şi *K. pneumoniae* producătoare de beta-lactamaze cu spectru extins (BLSE) au fost descrise ca infecţii nosocomiale sau asociate serviciilor de îngrijiri medicale. Totuşi, date recente sugerează implicarea acestor microorganisme producătoare de BLSE şi în infecţii comunitare (6).

Deşi diabetul este recunoscut ca factor de risc pentru numeroase infecţii, un număr mare de factori amplifică eforturile de a stabili riscul infecţiei şi al complicaţiilor acesteia, studiile specifice comparative cu pacienţii non-diabetici fiind rare**.** Datele referitoare la rezistența *E. coli* și *Klebsiella spp*. la acest grup de pacienți imunodeprimați sunt în permanentă schimbare. Pentru acest motiv am evaluat profilul rezistenței la antibiotice al acestor microorganisme comparativ la pacienți diabetici și pacienți fără diabet.

MATERIAL ŞI METODĂ

S-a realizat un studiu caz-martor retrospectiv, în perioada ianuarie 2009-ianuarie 2011, în care am inclus 199 pacienți internați în Spitalul Clinic de Boli Infecțioase "Sf. Parascheva" Iași de la care s-au izolat tulpini de *E. coli* și *Klebsiella spp*. din diferite produse patologice. Pentru pacienții cu infecții recurente au fost incluse doar izolate de la primul episod infecțios. Cazurile au fost reprezentate de pacienții diagnosticați cu diabet zaharat (DZ) anterior internării și pacienți cu DZ de novo, decelați odată cu internarea în clinică. Din totalul populației studiate 49 pacienți cu diabet și 150 fără diabet. Criteriul utilizat pentru excluderea pacienților diabetici posibili din grupul de pacienți fără diabet a fost absența antecedentelor de DZ și glicemie bazală mai mică de 126 mg/dl. Au fost înregistrate date demografice (vârstă, sex), spitalizare și antibioterapie anterior internării în clinică, prezența sau absența sondei urinare. Infecțiile au fost clasificate în funcție de date clinice și de laborator. Riscul de infecții cu tulpini rezistente a fost apreciat prin evaluarea scorului Carmeli.

Testarea rezistenței la antibiotice a izolatelor bacteriene a fost realizată prin metoda standard difuzimetrică (CLSI) și E-test. A fost realizată o bază de date în Excel care a fost prelucrată ulterior cu ajutorul programelor *SPSS 16.0* și *Epi Info 3.5.1*. Variabilele studiate au fost analizate descriptiv și analitic și s-au considerat semnificative statistic valorile p< 0,05.

REZULTATE ŞI DISCUŢII

În timpul perioadei studiate din 199 pacienți, 39 erau diagnosticați cu diabet zaharat în momentul internării, iar la 10 pacienți infecţia a fost evenimentul declanşator al instalării dezechilibrului metabolic glucidic. Astfel au fost incluși în studiu 49 de cazuri (79,5% au fost femei), cu o vârstă medie de 66,2 ani. Pacienții non diabetici (43 bărbați, 107 femei) au avut vârste cuprinse între 1-83 ani (media 46,29 ani).

Au fost izolate 133 tulpini de *E. coli* (37 la diabetici și 96 la non-diabetici). Majoritatea tulpinilor au fost izolate din urocultură (UC) (93,9%). Doar la 2 cazuri de diabet a izolată *E. coli* din hemocultură (HC) și UC (o tulpină sensibilă la toate antibioticele testate, o tulpină rezistentă la fluoroquinolone (FQ) și amoxicilină-acid clavulanic). La pacienți non-diabetici au fost izolate tulpini și din HC (un caz), spută (2 cazuri), puroi (2 cazuri), secreții lohii (un caz). Tulpinile de *E. coli* producătoare de BLSE au fost izolate din UC la majoritatea cazurilor, doar la două cazuri la non-diabetici fiind izolate din puroi și spută.

TABELUL I

Rata de izolare a *E. coli* si *K. pneumoniae* la pacienți diabetici si non-diabetici

Microorganism izolat	Pacienți diabetici Nr/%	Pacienți non diabetici Nr/%
E. coli	37/27,8	96/72,1
E. coli ESBL+	5/13,5	16/16,6
Klebsiella spp.	12/18,1	54/81,8
K. pneumoniae ESBL+	6/50	13/24
Total *E.coli* + *K. pneumoniae* ESBL+	11/22,4	29/19,33

TABELUL II

Factori de risc asociați cu infecția cu *E. coli* si *K. pneumoniae* BLSE pozitive

Variabilă	DZ	NON DZ	OR*	IC	P	Semnificație statistică
Vârsta peste 60 ani	6	13	1,48	0,30 – 7,41	0,84	NS

*pentru valori < 5, s-a aplicat corecţia Yates; SS = semnificativ statistic;NS = nesemnificativ statistic; AB=antibiotice

Din 66 tulpini de *Klebsiella spp*., *K. pneumoniae* a fost izolată din UC la toți 12 pacienți diabetici, tulpini BLSE pozitive fiind depistate în jumătate din cazuri. (tab. I) În lotul de non-diabetici, din UC au fost izolate 59 tulpini (o tulpină de *K. oxytoca*, BLSE negativă), 13 fiind tulpini BLSE pozitive. Câte 1 tulpină de *K. pneumoniae* fost izolată respectiv din HC, lichid cefalorahidian, 3 din aspirat traheo-bronșic și 2 din puroi (în asociere cu *Staphylococcus aureus*, respectiv *Enterobacter spp*.).

Dintre cele 11 cazuri de diabet la care au fost identificate tulpini de *E.coli* și *K. pneumoniae* producătoare de BLSE, 6 cazuri aveau vârsta peste 60 ani, doar 3 cazuri au primit antibioterapie în ultimele 3 luni anterior spitalizării. Toate cazurile de diabet au avut scor Carmeli 3 (tab. II). În studiul nostru ratele rezistenței *E. coli* la antibiotice la diabetic comparative cu lotul de non-diabetici au fost: amoxicilină-acid clavulanic 31,4% vs. 13,98%, p=0,04; ceftazidimă 16,7 vs. 12%, p=0,70; ciprofloxacină 52,9% vs. 24,46%, p=0,004; gentamicină 13,3% vs. 21,5%, p=0,52. Rata rezistenței la cotrimoxazol a fost similară în cele 2 loturi (p=0,7). Nu au fost tulpini rezistente la imipenem la nici unul din grupuri. Este de remarcat o rezistență scăzută la cefoxitin atât la diabetici cât și la non-diabetici (11,76% vs. 4,7%; p=0,57). Doar una din 23 respectiv 16 tulpini testate au fost rezistente la nitrofurantoin, respectiv colimicină în grupul cu diabet (tab. III).

TABELUL III

Sensibilitatea la antibiotice a tulpinilor de *E. Coli*

Antibiotic	Pacienți diabetici	Pacienți non-diabetici	p
	Tulpini rez. /Tulpini testate N/%	Tulpini rez. /Tulpini testate N/%	
Amoxi-ac. clav.[#]	11/35 (31,4)	13/93(13,98)	0,04
Cefotaxim	6/34 (17,6)	9/45 (20)	0,97
Ceftazidimă	6/36 (16,7)	9/75 (12)	0,70
Cefoxitin	2/17(11,76)	4/85 (4,7)	0,57
Imipenem	0/8	0/89	-
Ciprofloxacin	18/34 (52,9)	23/94 (24,46)	0,004
Gentamicină	4/30 (13,3)	16/76 (21,05)	0,52
Amikacină	0	5/58 (8,62)	-
Cotrimoxazol	11/20 (55)	5/9 (55,5)	0,70
Nitrofurantoin	1/23 (4,34)	0	-
Colimicină	1/16 (6,25)	0	-
Tulpini multirezistente	6 (16,2)	8 (8,3)	0,31

* Tulpini multirezistente la 3 clase de ATB*: FQ, CG3 (ceftazidimă, cefotaxim), aminoglicozide; [#]amoxicilină-acid clavulanic; rez=rezistente

La pacienții diabetici s-a înregistrat un procent mai mare de tulpini de *K. pneumoniae* rezistentă la amoxicilină-acid clavulanic (54,55%), comparativ cu cei non-diabetici (39,6%), diferența fiind însă nesemnificativă din punct de vedere statistic (p>0,05). Rezistența la CG3 este de asemenea mai mare la diabetici.

TABELUL IV

Sensibilitatea la antibiotice a tulpinilor de *Klebsiella spp.*

Antibiotic	Pacienți diabetici	Pacienți non-diabetici	P
	Tulpini rez. /Tulpini testate N/%	Tulpini rez. /Tulpini testate N/%	
Amoxi-ac. clav.[#]	6/11 (54,55)	21/53 (39,6)	0,56
Cefotaxim	6/8 (75)	20/44 (45,5)	0,24
Ceftazidimă	7 /10(70)	20/45 (44,4)	0,26
Cefoxitin	1/9 (11)	11/39 (28,2)	0,52
Imipenem	0	2/37 (5,4)	-
Ciprofloxacin	9 /12(75)	21/54 (39)	0,05
Gentamicină	6 /10(60)	17/46 (37)	0,32
Amikacină	1 /5(20)	1/13 (7,7)	0,92
Cotrimoxazol	3/3 (100)	11/15 (73,3)	-
Nitrofurantoin	2/2 (100)	-	-
Colimicină	0/3	-	-
Tulpini multirezistente [*]	6 (50)	18 (33,3)	0,45

* Tulpini multirezistente la 3 clase de ATB*: FQ, CG3 (ceftazidimă, cefotaxim), aminoglicozide; [#]amoxicilină-acid clavulanic; rez=rezistente

La lotul de diabetici doar una din 9 tulpini de *K. pneumoniae* a fost rezistente la cefoxitin, comparativ cu lotul de non-diabetici (28,2%, p=0,52). Nu a fost nici o tulpină rezistentă la imipenem în grupul de diabetici. Rezistența la ciprofloxacină a înregistrat valori semnificativ mai mari la pacienții diabetici (75% *vs* 39%; p=0,05). La diabetici au fost decelate rate de rezistență crescute și la gentamicină, cotrimoxazol, nitrofurantoin, dar numărul mic de cazuri nu conferă semnificație statistică. (tab. IV)

DISCUŢII

Datele raportate în 2007 de către Sistemul de Supraveghere Europeană al Rezistenței la Antibiotice (EARSS) referitoare la tulpinile de *E. coli* arată faptul că, cea mai crescută rată a rezistenței a fost înregistrată pentru amino-peniciline, între 26% și 77 %. Rapiditatea cu care FQ își pierd activitatea împotriva *E.coli* este de neegalat, în 25 din 28 de țări evidențiindu-se o rezistență în creștere la acest grup de antibiotice (5).

Într-un studiu multicentric efectuat în 2007 în România, pentru *E. coli* datele au relevat 24,21% rezistență la FQ și 15,23% rezistența la cefalosporine de generația a 3-a (CG3). De asemenea, este de notat o sensibilitate în creștere la piperacilină-tazobactam și nitrofurantoin (4). În studiul prezent au fost înregistrate diferențe doar pentru amoxicilină-acid clavulanic și ciprofloxacină, rezistența în lotul de cazuri fiind semnificativ mai mare (31,4% *vs.*13,98%, p=0,04, respectiv 52,9% *vs.* 24,46%, p= 0,004) (tab. III).

Rezistența combinată survine frecvent, co-rezistență la patru clase de antibiotice, inclusive CG3 este deja una dintre cele mai comune patru forme de rezistență întâlnită în infecția invazivă cu *E. coli*, tendință în creștere în Europa (5).

În cercetarea noastră, multi-rezistența tulpinilor de *E. coli* nu a prezentat diferențe

semnificative între cele 2 grupuri (16,2% *vs*. 8,3%, p=0,31). Infecţii cu tulpini de *E. coli* BLSE pozitive au fost înregistrate doar la femei diabetice, un procent ridicat prezentând şi femeile fără diabet (62,5%).

În nouă studii europene publicate din 1990, doar 14 (2.3%) din 621 pacienţi au fost spitalizaţi pentru pneumonie comunitară severă având ca agent etiologic probabil *K. pneumoniae*. În Africa şi Asia, în schimb, pneumonia comunitară continuă să fie asociată cu *K. pneumoniae*. Într-un studiu prospectiv al lui Wen-Chien Ko şi colab. pneumonia comunitară însoţită de bacteriemie a fost raportată la 12 din 21 dintre pacienţii diabetici. Manifestări clinice distincte cu *K. pneumoniae* (abces hepatic, meningită, endoftalmită) comparate cu alte infecţii bacteriemice comunitare au fost semnificativ asociate cu DZ (60% vs 28%, p=0,0015) şi rezidenţa în Taiwan (3).

În studiul nostru jumătate din cazurile cu *K. pneumoniae* au fost diagnosticate cu sepsis, iar restul cu infecţii ale tractului urinar. La pacienţii diabetici au fost izolate mai multe tulpini producătoare de BLSE comparativ cu lotul de non-diabetici (50% vs. 24%) (tab. I). Majoritatea cazurilor cu tulpini BLSE pozitive au fost raportate la femei diabetice (83,3% vs. 38,5%) (tab. II). Referitor la factorii de risc asociaţi infecţiilor cu tulpini de *K. pneumoniae* BLSE pozitiv, doar 2 din 12 pacienţi diabetici au avut spitalizare anterioară, ceea ce ar sugera o tendinţă la emergenţa acestor tulpini şi în infecţii comunitare.

EARSS a evidenţiat, în studiul efectuat în 2007, o prevalenţă crescută în Europa de Est şi de Sud-Est a tulpinilor de *K. pneumoniae* rezistente la CG3, FQ şi aminoglicozide, cel mai frecvent fenotip fiind multi-rezistent la toate cele trei clase de antibiotice. În studiul nostru am remarcat o rată mai mare a multi-rezistenţei la pacienţii diabetici, comparativ cu cei non-diabetici (50% *vs*. 33,3%).

CONCLUZII

Rezistenţa crescută la fluoroquinolone şi la cefalosporinelede a 3-a generaţie observată şi în studiul nostru ar trebui să limiteze utilizarea acestora în terapia empirică, carbapenemele, aminoglicozidele şi colimicina reprezentând opţiuni ale terapiei de primo-intenţie. Recunoaşterea promptă şi abordarea multidisciplinară a infecţiilor comunitare sau nosocomiale, cu microorganisme multi-rezistente la bolnavul diabetic, cu monitorizarea strictă a dezechilibrelor metabolice şi intervenţia chirurgicală la timp sunt esenţiale pentru scăderea morbidităţii şi mortalităţii acestui grup.

NOUTĂȚI

ASOCIEREA DISFUNCȚIEI OLFACTIVE CU MANIFESTĂRILE NEUROPSIHIATRICE ÎN BOALA PARKINSON

Manifestările non-motorii ale bolii Parkinson includ, în mod uzual, hiposmia, deficitul cognitiv şi afectarea psihiatrică, deşi legătura dintre ele este încă incomplet înţeleasă. Relaţia dintre disfuncţia olfactivă şi afectarea neuropsihiatrică a fost investigată prin intermediul unui studiu pe 248 de pacienţi înrolaţi din două clinici specializate în afectări ale mişcării. Analiza psihiatrică a inclus următoarele teste: GDS-15 (Geriatric Depression Scale-15), Inventarul Simptomelor Depresive, testul pentru Investigarea Statusului Anxios, Scala de Apatie şi Scala de Psihoză a bolii Parkinson. Analiza statusului cognitiv a inclus MMSE-ul (Mini Mental State Examination), Testul de Învăţare Verbală Hopkins, Testul Culoare-Cuvânt Stroop. Funcţia olfactivă a fost evaluată prin Testul de Identificare a Mirosurilor elaborat de Universitatea din Pennsylvania. Nici o asociere statistic semnificativă între olfacţie şi nivelul dispoziţiei pacienţilor nu a fost evidenţiată. Cu toate acestea, simptomele psihotice au fost mai frecvent înregistrate mai frecvent la acei pacienţi cu scoruri ale simţului olfactiv sub valoarea mediană (30% vs. 12%; $P < 0.001$). O capacitate olfactivă mai slabă a fost asociată cu o afectare mai severă a memoriei, iar scorul obţinut la Testul de Identificare a Mirosurilor a fost un factor predictiv important pentru rezultatul obţinut la testele cognitive. Relaţia dintre hiposmie, psihoză şi deficitele cognitive specifice ar putea reflecta distribuţia anatomică a corpilor Lewy; astfel, disfuncţia olfactivă ar putea reprezenta un marker adiţional pentru boala extranigrală. REGENERAREA NERVULUI PERIFERIC. STUDIU EXPERIMENTAL - REZULTATE DEFINITIVE

Mihaela Perţea[1], S. Luncă[2]
Universitatea de Medicină şi Farmacie "Gr. T. Popa" Iaşi
Facultatea de Medicină
1. Clinica de Chirurgie Plastică şi Microchirurgie Reconstructivă
Spitalul Clinic de Urgenţe "Sf. Ioan" Iaşi
2. Clinica de Urgenţe Chirurgicale

REGENERATION CAPACITY OF THE PERIPHERAL NERVE: EXPERIMENTAL STUDY -FINAL RESULTS (Abstract): Any injury affecting peripheral nerve continuity is followed by a degenerative reaction from nerve itself and its muscle. Nerve regeneration is possible when the two ends are put in direct contact (direct suture), proximity (autologous or artificial grafts), or through muscle neurotization. The aim of this experimental study was to evaluate sciatic nerve degeneration and regeneration in rats after no suture (group 1), direct suture (group 2), nerve grafting (group 3) and muscle neurotization (group 4). Nerve samples were analyzed by optical microscopy at 8 and 16 weeks after surgery, and nerve degeneration (group 1), axonal growth (group 2) and neuromuscular regeneration (group 4) were assessed. Optical microscopy and different staining techniques confirmed nerve degeneration, regeneration, and axonal growth in different moments. Cholinesterase test after direct muscle neurotization showed enzymatic activity at the level of muscle implantation of nerve fibers, indirectly confirming the presence of neuromuscular synapse. **Key words**: PERIPHERAL NERVE INJURY, NERVE DEGENERATION, NERVE REGENERATION, MUSCLE NEUROTIZATION

Alterarea continuităţii nervului periferic, indiferent de cauză (striviri, compresiuni sau secţiuni) determină un proces de degenerare urmat firesc de tenativa de reparare, atât morfologică cât şi funcţională, proces reprezentat de reorganizarea structurală şi reacţiile metabolice (reacţii axonale) (1-4). Acest proces este posibil numai atunci când capetele nervului secţionat sunt în apropiere unul de celălalt. Prin regenerare se stabilesc conexiunile dintre centrii nervoşi şi organele terminale. Există o multitudine de tehnici chirurgicale prin care se obţine apropierea sau contactul direct dintre capetele secţionate ale unui nerv periferic, condiţie necesară debutului regenerării nervoase (1, 3-5).

Tehnicile chirurgicale prin care se restabileşte continuitatea fibrelor nervoase, în cazul secţiunii nervului periferic, pot include sutura directă, grefa de nerv (atunci când mărimea defectului nu permite sutura directă). În cazul defectelor de nerv pot fi utilizate şi alte ţesuturi, cum ar fi vena, muşchi în venă sau materiale sintetice de tipul tuburilor de silicon, pentru a putea crea un culoar de direcţionare a creşterii axonale (6-9). În cazul în care dimensiunea defectului nu permite utilizarea nici uneia

dintre aceste tehnici (acesta fiind mult prea mare sau ca urmare a smulgerii capătului distal), se va utiliza implantarea fibrelor nervoase direct în mușchi, tehnică numită neurotizare neuromusculară. Tehnica include disecția și separarea fibrelor nervoase și implantarea acestora în mușchi prin mici incizii practicate în acesta din urma, incizii realizate la profunzimi diferite în grosimea mușchiului. Se vor obține, prin acestă tehnică chirurgicală, formarea de noi sinapse neuromotorii la nivelul de implantare a fibrei nervoase în mușchi (10-12).

Scopul acestui studiu este de a pune în evidență, prin metode histologice, capacitatea de regenerarea axonală la nivelul unui nerv suturat direct, al unuia reconstruit prin interpunerea unei grefe de nerv, dar și punerea în evidență, prin utilizarea unor reacții enzimatice a formării sinapsei neuromotorii la locul de implantare a fibrei nervoase în mușchi atunci când este utilizată tehnica neurotizării neuromusculare.

MATERIAL ŞI METODĂ

Studiul actual urmăreşte a completa rezultatele preliminare prezentate într-un număr anterior al revistei (2). Studiul a fost realizat pe un lot de 30 de şobolani Wistar, femele, cu vârsta de 8 săptămâni şi greutăți cuprinse între 190 şi 220 de grame. Animalele au fost găzduite individual într-un mediu controlat 24 ore din 24 şi acces liber la apă şi alimente. Aclimatizarea animalelor s-a făcut cu 10 zile anterior intervențiilor chirurgicale. Cele 30 de animale nu au primit alimente cu o noapte înainte de intevenția chirurgicală. Sub anestezie generală, s-a descoperit nervul sciatic la nivelul membrului posterior drept, urmată de secționarea acestuia. Animalele au fost împărțite în 4 loturi în funcție de intervenția chirurgicală de care au beneficiat. Primul lot a cuprins un număr de 6 animale, la care nervul sciatic nu a fost suturat. În cazul celui de al II-lea lot, format dintr-un număr de 8 animale, s-a practicat sutura directă a nervului sciatic. Pentru lotul al III-lea, format dintr-un număr de 8 animale, reconstrucția nervului sciatic s-a efectuat prin interpoziția unei grefe de nerv liberă nevascularizată. Al IV-lea lot a inclus 8 animale, iar în acest caz s-a utilizat tehnica neurotizării neuromusculare, în care după disecția pe fascicule a nervului sciatic, s-a practicat implantarea acestora în mușchiul pe care îl inervează (fig. 1-5).

Implantarea fibrelor nervoase în mușchi s-a realizat pe diferite suprafețe și la diferite adâncimi, urmărindu-se punerea în evidență a sinapselor neuromotorii nou formate la acest nivel, și implicit utilitatea acestei tehnici chirurgicale.

Fig.1. Secțiune nerv sciatic

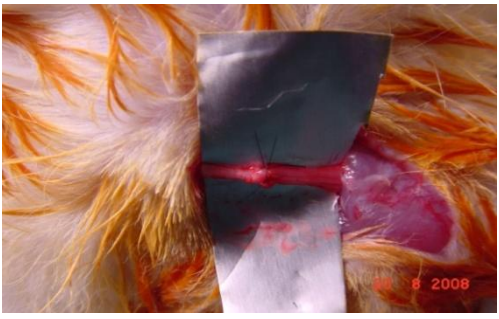

Fig. 2. Neurorafie directă nerv sciatic (lot I)

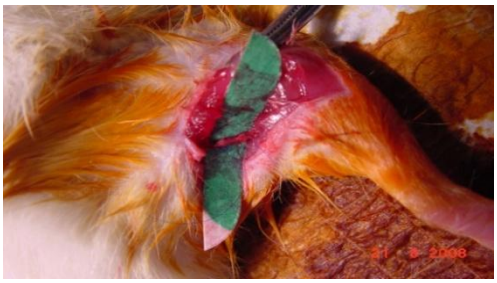

Fig. 3. Grefă de nerv (lot III)

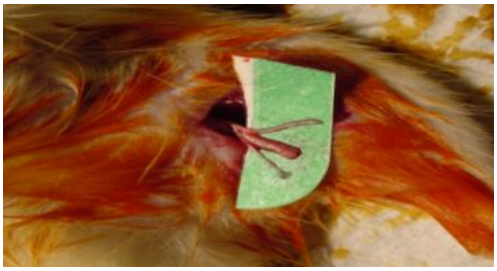

Fig. 4. Disecţia nervului sciatic în fascicule

Fig.5. Neurotizare neuromusculară directă (lot IV)

Un număr de 7 şobolani din lotul al III-lea au decedat în perioada postoperatorie imediată.

Lotul de 30 de animale a fost împărţit în două subloturi (A şi B) în funcţie de momentul în care s-a realizat recoltarea pieselor de analizat. Lotul A, la care recoltarea s-a efectuat la 8 săptămâni postoperator, a cuprins 11 animale (3 din lotul I, 4 din lotul II, 4 din lotul 4). Lotul B, la care recoltarea a fost realizată la 16 săptămâni de la operaţie a cuprins un număr de 12 animale (3 din lotul I, 4 din lotul II, 1 din lotul III si 4 din lotul IV).

Pentru studiul histologic, în toate cazurile, a fost folosită microscopia optică prin tehnica includerii la parafină. În prima etapă de colorare a secţiunilor s-au utilizat atât metode uzuale: coloraţia hematoxilină–eozină (HE) şi coloraţia tricromică (van Gieson), cât şi metode speciale: coloraţia tricromică C. Szekely şi coloraţia Gordon-Sweet. Pentru a pune în evidenţă sinapsele nou formate, în cazul implantării fibrelor nervoase direct în muşchi (neurotizare neuromusculară), s-a utilizat o reacţie enzimatică – tehnica colinesterazei. Tehnica colinesterazei sau metoda tiocolinei, propusă în 1959 de către Gerebtzoff, are la bază hidroliza substratului de acetiltiocolină de către activitatea enzimatică pentru producerea tiocolinei. Tiocolina se combină cu ionii de cupru prezenţi în mediul de incubare pentru a forma cupru-tiocolina. Precipitatul astfel format nu este vizibil în lumina microscopului. Fiind tratat cu o soluţie de sulfat de amoniu, va forma cupru-sulfatul, recunoscut astfel ca un precipitat de culoare maro, punându-se astfel în evidenţă activitatea enzimatică şi indirect a sinapselor nou formate.

REZULTATE

Rezultatele definitive le-au completat pe cele preliminare (prezentate într-un articol anterior) făcând comparaţia, din punct de vedere histologic, a zonelor de regenerare, în cazul diferitelor tipuri de tehnici de reconstrucţie nervoasă utilizate. Compararea s-a efectuat între cele două loturi, apreciindu-se astfel progresia regenerării. De această dată (faţă de studiul preliminar) evaluarea modificărilor degenerative cât şi a regenerării s-a făcut şi cu metodele speciale de colorare.

Pe animalele din primul lot, la care recoltarea s-a făcut la 8 săptămâni postoperator, s-au constatat inițial modificări degenerative incipiente cu fragmentarea fibrelor nervoase. La animalele din cel de-al II-lea lot, la care recoltarea s-a efectuat la 16 săptămâni, fenomenele de degenerare progresează, în structura nervului fiind remarcate fragmentări axonale mai importante. Modificări de acelaşi tip apar şi la nivelul mușchiului, degenerarea la nivelul fibrelor musculare fiind reprezentată de omogenizarea fibrelor şi dispariția nucleilor (fig. 6,7).

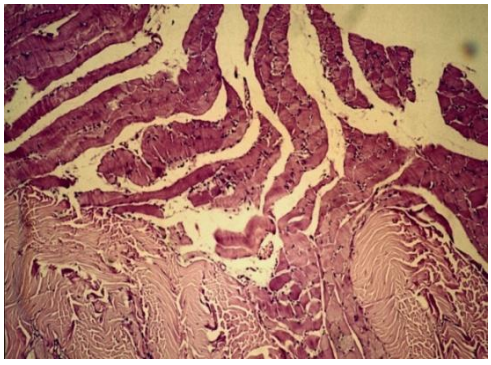

Fig. 6. Mușchi scheletal. Arii cu modificări degenerative ale fibrelor musculare, dispariția nucleilor, omogenizarea fibrelor (HE 20x)

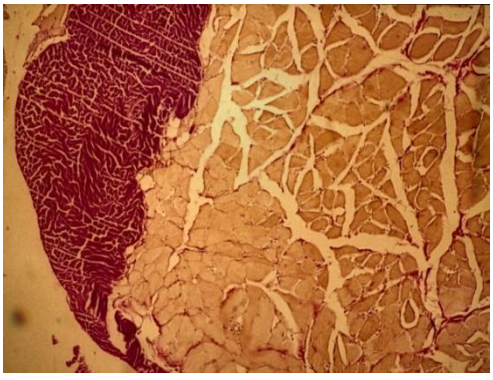

Fig. 7. Mușchi scheletal. Zonă cu modificări degenerative (van Gieson 20x)

Degenerarea a fost remarcată atât cu ajutorul tehnicii de colorare cu hematoxilină–eozină, cât şi în coloraţia van Gieson (fig. 8). Tehnica pentru reticulină evidențiază în nervul degenerat, zone restrânse de discontinuitate, în majoritate tecile Schwann cu membrana lor bazală păstrându-şi continuitatea (fig. 9). În aceeaşi coloraţie pentru reticulină, în zona musculară alterată, se remarcă o densificare a fibrelor reticulare cu apariția de fibre fine suplimentare, care gâtuie în cea mai mare parte fibrele musculare.

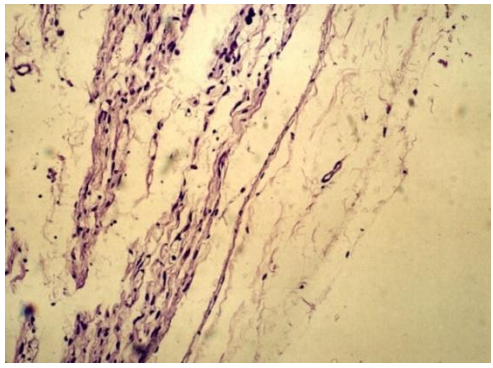

Fig. 8. Nerv periferic secționat, fragmentări axonale pronunțate (HE10x)

Fragmentul de nerv sciatic, recoltat la 8 săptămâni (lotul I), din segmentul distal neurorafiei, prezintă în coloraţia HE o reorganizare a histoarhitectonicii. Nucleii celulelor Schwann formează din nou şiraguri orientate în lungul nervului, iar în jurul lor există o cantitate mai mare de citoplasmă, cu o nuanță mai bazofilă. Printre fasciculele nervoase, din loc în loc, se observă mici lumene vasculare (fig. 9). După impregnare argentică, fibrele reticulare apar relativ paralele, în mare parte cu continuitate păstrată şi numai în unele zone se remarcă mici discontinuități (fig. 10). Țesutul muscular prelevat din zona distală neurorafiei, în cadrul aceluiaşi lot I, prezintă în

coloraţie HE, mănunchiuri de fibre eozinofile, cu nuclei periferici, organizate în fascicule, separate prin perimisium (fig. 11).

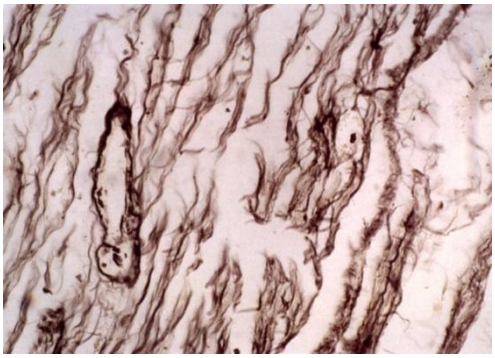

Fig. 9. Nerv periferic secţionat, fragment distal, modificări incipiente. (reticulină, impregnaţie argentică 40x)

Histoarhitectonia ţesutului muscular este păstrată. Impregnaţia argentică evidenţiază prezenţa fibrelor reticulare în endomisium, cu o perfectă organizare. În ceea ce priveşte lotul la care s-a utilizat neurotizarea neuromusculară, în cazul recoltării la 8 săptămâni postoperator, fragmentele de ţesut muscular prezintă aspecte diferite. În unele zone, la nivelul epimisiumului se remarcă lumene vasculare, ţesut adipos şi mici fascicule de fibre nervoase în vecinătatea unor fibre musculare striate, izolate între ele de ţesut conjunctiv bogat în adipocite (fig. 12). În alte zone, se remarcă la nivelul perimisiumului, fibre nervoase într-o atmosferă de ţesut conjunctiv lax. În preparatele tratate cu impregnaţie argentică, mănunchiurile de fibre nervoase apar evidente în perimisium, iar reţeua de fibre reticulare din ţesutul muscular învecinat, prezintă arhitectonie nemodificată. Prin tehnica de colorare tricromă, se remarcă prezenţa de mici fascicule de fibre nervoase în perimisiumul dintre fasciculele musculare striate (fig. 13). În zona de neurotizare, organizarea histoarhitectonică şi structura microscopică a fibrelor musculare striate, a fost integră, aspect evidenţiat atât în secţiuni longitudinale cât şi transversale.

Fig. 10. Nerv periferic cu neurorafie, segment distal.
(Reticulină impregnaţie argentică 40x)

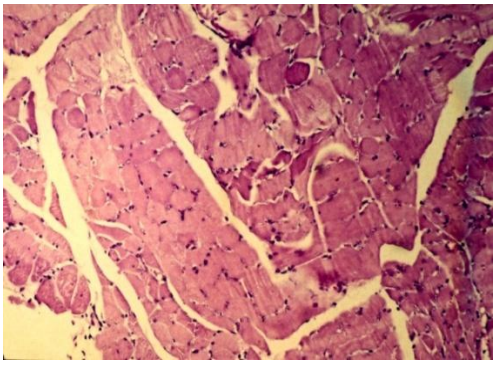

Fig. 11. Muşchi scheletal din zona de neurorafie. Structură conservată - HE (lot I)

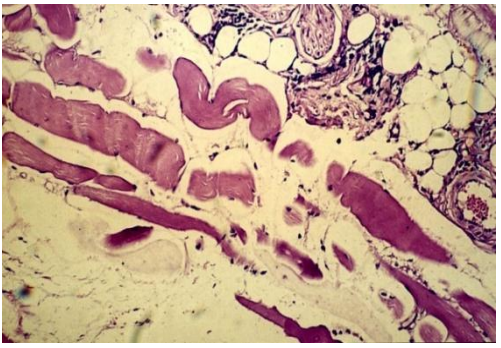

Fig. 12. Fibre nervoase în vecinătatea unor fibre musculare striate - HE 20x (lot I)

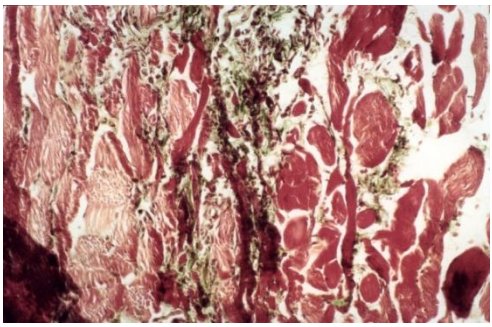

Fig. 13. Zonă de neurotizare. Fibre nervoase în vecinătatea fibrelor musculare - Tricrom Szekely 20x (lot I)

Fig. 14. Nerv periferic după neurorafie. Reticulină, impregnație argentică 20x (lot II)

În cazul lotului II, la care recoltarea s-a efectuat la 16 săptămâni postoperator, în colorație HE, segmentul distal al neurorafiei directe arată în secțiune longitudinală o structură conservată. Fibrele nervoase sunt organizate ordonat în ax longitudinal cu discrete sinuozități, cu celule Schwann aranjate în şiraguri, cu o densitate mai mică comparativ cu primul lot. Acelaşi fragment tratat pentru evidențierea fibrelor reticulare, arată o organizare a acestora în mănunchiuri orientate în axul lung al nervului, dispuse paralel şi cu un traiect uşor sinuos (fig. 14). În cazul neurotizării, unele fascicule musculare prezintă morfologie care sugerează regenerarea musculară avansată. Impregnarea argentică evidențiază un filet nervos într-o relație intimă cu fasciculele musculare (fig. 15). În numeroase arii examinate s-au pus în evidență pachete vasulo-nervoase ataşate suprafețelor musculaturii striate. Fragmentele musculare din zona de neurotizare au scos în evidență existența unor nervi periferici de dimensiuni diferite în perimisiumul țesutului muscular striat. Colorația tricromică scoate în evidență, deasemenea, prezența de fine fascicule nervoase în epimisium, în imediata vecinătate a fasciculelor musculare (fig. 16).

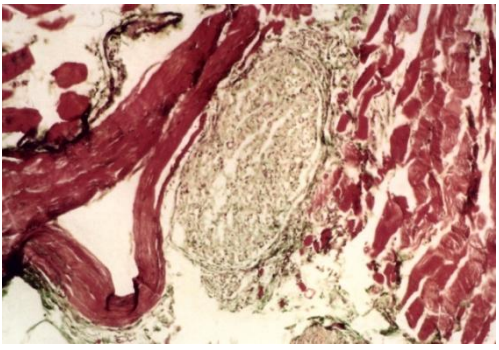

Fig. 16. Zonă de neurotizare. Mic nerv periferic şi lumen vascular printre fasciculele musculare. Tricrom Szekely 20x (lot II)

Depistarea sinapselor neuromusculare efectuată prin reacția histoenzimologică pentru colinesterază, a evidențiat prezența unei reacții pozitive de intensitate cores-

punzatoare, la nivelul fibrelor musculare striate, din zonele de neurotizare. Densitatea ariilor cu reacţii pozitive a fost variabilă, rămânând constant prezentă (fig. 17, 18).

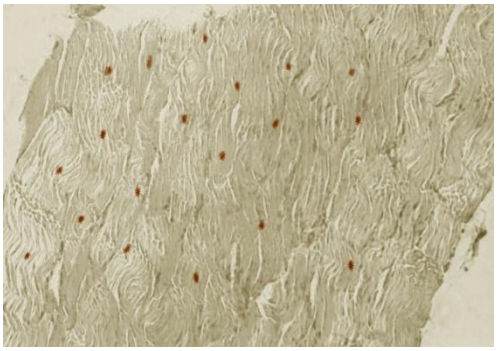

Fig. 18. Zonă de neurotizare: fibre musculare striate, prezenţa unor sinapse (secţiune longitudinală). Colinesterază 40x (lot II)

DISCUŢII

Capacitatea mare de regenerare a sistemului nervos periferic este dată de organizarea sa celulară. Orice traumatism la nivelul nervului periferic – strivire, secţiune sau smulgere – determină un proces de degenerare, care este urmat de tentativa de reparare morfologică şi funcţională. După denervare muşchiul îşi pierde contractilitatea voluntară şi devine flasc, mergând până la atrofie severă la un an de la leziune şi maximă la doi ani de la traumatism (13-15).

Traumatismele de la nivelul nervilor periferici sunt leziuni grave în urma cărora pacientul este scos din viaţa socială şi profesională pentru o perioadă lungă de timp. Repararea nervului periferic se face prin mai multe tehnici chirurgicale (sutura directă, grefa de nerv, neurotizare, etc), dar important este ca momentul la care se face reconstrucţia să fie cât mai aproape de cel al traumatismului (8, 9, 14,16).

Implantarea directă în muşchi a fibrelor nervoase dă posibilitatea formării de noi plăci neuromotorii gigante în zona aneurală a muşchiului, făcând astfel posibilă reinervarea muşchiului. Toate studiile făcute de-a lungul timpului au confirmat teoria neurotropismului şi sugerau că ţesutul nervos periferic este capabil de discriminarea unei ţinte specifice (10, 17, 18).

Studiul descris confirmă prezenţa modificărilor care au loc la nivelul capetelor unui nerv traumatizat (secţionat), precum şi modificările existente în muşchiul denervat.

La nivelul nervului periferic s-au observat alterările caracteristice degenerării walleriene, manifestate prin fragmentări ale fibrelor nervoase, constatate precoce, însoţite de modificări la nivelul tecii Schwann şi ale endonervului (19-21).

Pe preparatele examinate s-au putut constata zone de creştere ale celularităţii de-a lungul fibrelor nervoase din segmentul distal al nervului secţionat, datorită migrării macrofagelor şi stimulării celulelor Schwann, observaţie în concordanţă cu datele din literatură (6). Atrofia neurogenă s-a manifestat prin reducerea pronunţată în dimensiuni a fibrelor musculare cu angularea acestora şi apariţia modificărilor tinc-

torialității cu afinitate înspre fuxina acidă.

În prezent, se admite că regenerarea fibrelor nervoase pe seama segmentului proximal, începe imediat după secționarea nervului şi că eliberarea factorilor de creştere neurali (NGF) de către fibroblaste în matricea extracelulară a segmentului distal şi că expresia receptorilor NGF de către celulele Schwann creează un micromediu favorabil regenerării axonale (22, 23).

În experimentul efectuat, efectele favorabile ale neurorafiei s-au putut observa la ambele loturi, dar mai evident la cel de-al II-lea. În tehnica pentru reticulină, fibrele reticulare şi-au păstrat în mare măsura organizarea la nivelul bontului distal după neurorafie, ceea ce susține ideea că membrana bazală (care conține colagen IV şi colagen III) se reorganizează foarte precoce pe seama celulelor Schwann.

În ambele loturi, după practicarea neurorafiei s-au putut constata arii de fibre musculare striate fără modificări, sau arii restrânse cu aspect microscopic de regenerare. Acest aspect sugerează că regenerarea se realizează în mod progresiv în etape, în raport cu diferitele unități neuromotorii (4, 23).

În ceea ce privește neurotizarea neuromusculară s-au observat la ambele loturi, dar mai ales la cel de-al II-lea, numeroase structuri de tip nerv periferic, unele cu dimensiuni foarte înguste, aparent formate din 8-15 fibre nervoase cu tecile aferente prezente printre fibrele musculare striate, într-o atmosferă de țesut conjunctiv lax.

Observațiile studiului sugerează păstrarea în viața adultă a capacității fibrei nervoase de a răspunde la factorii locali de creştere, sintetizați în principal la nivelul țesutului conjunctiv, unde un rol important îl joacă laminina. Există de asemenea, factori care atrag conurile de creştere neuronală spre anumite ținte. În cazul neuronilor motori, conurile de creştere sunt atrase de către fibrele musculare de care aderă (10, 17, 18). Se consideră că sub efectul neurotransmițătorilor se vor organiza sinapse, realizându-se o inervare polineurală, care este tranzitorie şi care în final va deveni mononeurală prin eliminarea sinapselor mai puțin active. În experimentul prezent am putut constata variate relații de apropiere între fibrele nervoase şi fibrele musculare (2, 12, 25).

Cu ajutorul reacției histoenzimologice pentru evidențierea colinesterazei din sinapsă, am putut demonstra prezența sinapselor colinergice la nivelul fibrelor musculare din zona de neurotizare, cu o densitate mai mică la lotul I şi mai mare la lotul II. Brunelli şi colab. au demonstrat că neurotizarea neuromusculară directă este mai eficientă atunci când implantarea fibrelor nervoase la nivelul mușchiului se face mai superficial, obținându-se astfel o capacitate contractilă mai înaltă. Toate acestea se datorează, se pare, unei activități mai mari a enzimelor glicolitice din fibrele musculare periferice, fiind astfel scăzută insuficiența aparatului de ghidare şi formarea micronevroamelor intramusculare la joncțiunea neuromusculară (2, 17-19).

În toate cazurile un rol important îl au factorii de creştere nervoasă care sunt sintetizați în țesuturile inervate de nervi simpatici şi senzitivi şi sunt transportați de axonii terminali la corpurile celulare unde îşi exercită funcția de supraviețuire şi rolul trofic.

În cazul tuturor traumatismelor de la nivelul nervului periferic, recomandarea este ca reconstrucția nervului să fie una imediată (în urgență), pentru a crea condiții bune debutului creşterii axonale (2, 12, 14, 16).

CONCLUZII

Se poate spune că leziunile de la nivelul nervilor periferici sunt extrem de importante atât datorită deficitului motor şi senzitiv de la nivelul segmentului afectat, cât şi perioadei de timp mari de la momentul reconstrucției la momentul reintegrării socio-profesionale a pacientului. Pentru a obține rezultate mai rapide şi de o bună calitate repararea nervului traumatizat trebuie facută la un moment cât mai apropiat de cel al traumatismului. Pentru reconstrucția de nerv este de dorit a se evita tensiunea pe linia de sutură, se preferă sutura directă în favoarea grefei de nerv atunci când este posibil. Neurorafia directă duce la reorganizarea histoarhitectonicii. Nucleii celulelor Schwann formează din nou şiraguri orientate în lungul axului nervului, iar în jurul lor se poate remarca o cantitate mai mare de citoplasmă, cu o nuanță mai bazofilă, dând aspect general de hipertrofie a celulelor Schwann. Din loc în loc, printre fasciculele nervoase se pot observa mici lumene vasculare. Fibrele reticulare apar relativ paralele, după impregnarea argentică, în mare parte cu continuitatea păstrată şi numai în unele zone apar mici discontinuități.

Formarea sinapselor în zonele de implantare a fibrelor nervoase în muşchi arată eficiența tehnicii de neurotizare pentru reinervarea muşchiului denervat. Reacția histoenzimologică pentru colinesterază a evidențiat prezența unei reacții pozitive de intensitate corespunzătoare la nivelul fibrelor musculare striate din zonele de neurotizare, ceea ce reprezintă depistarea sinapselor neuromusculare.

Regenerarea nervoasă depinde de o multitudine de factori, cei mai importanți fiind vârsta, nivelul traumatismului leziunile asociate, nervul afectat, momentul reparării nervoase, tehnica utilizată, tratamentul adjuvant.

SUTURELESS FUNCTIONALLY ADAPTIVE FIXATION METHOD FOR INGUINAL HERNIOPLASTY (Abstract): Mesh fixation using glue instead of sutures for inguinal hernia (IH) repair has become popular during last decade. Existing literature database including multiple clinical trials is confusing, giving no exact answer whether mesh fixation with glue can reduce chronic pain without increasing the recurrence rate and/or causing other glue related side effects. **Aim:** To determine whether the use of glue to fix the mesh reduce pain, postoperative complications and 18 months reoccurrence rates after IH repair compared to Lichtenstein technique. Secondary objectives were to compare quality of life changes after sutured and glued mesh fixation. **Material and methods:** The study involved 94 primaries uncomplicated IH patients divided into 2 groups: control group of 71 (75.53%) patients, who underwent classic sutured Lichtenstein repair and study group of 23 (24.47%) patients with glued mesh fixation according to developed functionally adaptive fixation (FAF) technique combining albumin glue mesh fixation and mesh tailoring in accordance to anthropometric peculiarities. **Results:** Duration and expression of post-operative pain requiring painkillers, length of working capacity and physical activity restoration was shorter in study group compared to control. Quality of life according to SF-36 was better following FAF surgery, too. **Conclusions:** FAF demonstrated better or comparable results with less acute and chronic postoperative pain and better quality of life than sutures for Lichtenstein hernia repair. No FAF specific complications were demonstrated in this study. Further prospective studies are at need with wider cohort selection, better randomization, and standardization combined with different surgical glues assessment. **Keywords:** HERNIA REPAIR, INGUINAL HERNIA, GLUE, MESH FIXATION, PAIN, QUALITY OF LIFE, SUTURE.

Inguinal hernia (IH) is the most common abdominal wall hernia. IH account for about 75% of all abdominal wall hernias, with a lifetime risk of 27% in men and 3% in women; up to 50% of patients with IH are unaware of this condition and IH repair is one of the most commonly performed surgical procedures worldwide, with rates ranging from 10 per 100 000 of the population in the UK to 28 per 100 000 in the US.

IH are at risk of irreducibility or incarceration, which may result in strangulation and obstruction (1).

Risk factors for IH are well known, including gender, physical activity, and older age. However, similarly to other diseases, genetic predisposition to IH and connective tissue abnormalities in general (2) is discussed backed by both gender-associated nature of disease, modern morphological findings (3) and pathogenesis analogies with other conditions.

Conservative management and manual hernia reduction may be only applied in uncomplicated asymptomatic or minimally symptomatic IH (without or only minimal complaints). Surgery is the treatment of choice varying from currently outdated natural (own) tissue hernioplasty to Lichtenstein mesh and laparoscopic (TEP preferred to TAPP) repair. Non-mesh hernioplasty, according to EHS Guideline is only recommended for strangulated hernia repair in case of suspected infection. Endoscopic hernia repair requires both equipment end expertise, is comparatively expensive and more effective in bilateral IH. Compared with open repair, laparoscopic surgery for IH is associated with longer operation times, higher recurrence rates, but less severe postoperative pain, fewer complications, and more rapid return to normal activities. Tension-free Lichtenstein hernioplasty is comparatively simple, affordable and effective technique for IH repair; it has relatively low recurrence and complications rates, but several side effects (4). Most important of them, chronic groin pain syndrome may be a long-term problem related to mesh sutured fixation and operative trauma after Lichtenstein hernioplasty. Collection of blood or fluid, local inflammation and neuropathy are considered to be related to mesh and its fixation with sutures (5, 6).

As a result, mesh fixation using glue instead of sutures has become popular during last decade (7, 8). Existing literature database including multiple clinical trials is confusing, giving no exact answer whether mesh fixation with glue can reduce chronic pain without increasing the recurrence rate and/or causing other glue related side effects.

Therefore, *the aim of this study* was to determine whether the use of glue to fix the mesh instead of sutures reduce acute postoperative pain, postoperative complications, chronic pain and 18 months reoccurrence rates after IH repair compared to the own tissues and Lichtenstein technique. Secondary objectives were to compare quality of life changes after sutured and glued mesh fixation.

MATERIAL AND METHODS

The study involved 94 (mean age 34.17±6.49 yrs.) primary uncomplicated IH patients divided into two groups: *the control group* of 71 (75.53%) patients, who underwent classic sutured Lichtenstein repair and *study group* of 23 (24.47%) patients with glued mesh fixation according to developed functionally-adaptive fixation (FAF) technique. This study *conforms to international bioethical standards* (European Convention on Human Rights and Biomedicine, the Declaration of Helsinki of the World Medical Association on ethical principles of scientific medical research involving human subjects, GCP, EUC directive #609, etc.) and approved by Commission for Bioethics in Research of the Bukovinian State Medical University, Ukraine. All patients signed written permissions and obtained full information about the study prior to participation. Local anesthesia was combined with sedation and systemic painkillers (6).

Lichtenstein hernia repair (control group) performed with non-absorbable

polypropylene sutures for fixation of lightweight polypropylene mesh. FAF method (study group) included: -evaluation of patient's morphological type, determination of anthropometric indicators (abdominal indices, *distantia spinarum*, height of hypogastrium, and distances from the pubic symphysis to *spina iliaca* anterior superior and from the pubic tuberculum to the inguinal ring etc.), and assessment of anatomical peculiarities e.g. trauma or connective tissue conditions; use of albumin-based glue containing 45% albumin and 10% glutaraldehyde solutions in 4:1 proportions for mesh fixation. The *concept of FAF* method is based on use of albumin glue, less influencing local tissues compared to more common fibrin or cyanoacrylate glues (9, 10), but which may comparatively rapidly degrade due to local and systemic fibrinolysis (anti-fibrinolytic agents were added) stimulated by both surgical trauma, bleeding and grafting similarly to other surgeries (11); and tailoring the mesh according to anthropometric peculiarities of the patient, somehow similarly to E. Trabuco's technique (12). The last assists in keeping the mesh fixed on-site, providing additional *elastic fixation* by own tissues.

Set of clinical data including postoperative complications, pain syndrome, impact on physical capacity, and recurrence were evaluated by an independent blinded observer. SF-36 questionnaire was used for quality of life after hernioplasty assessment. *Statistical processing* was carried out using the *MS Excel* software.

RESULTS

Duration of post-operative pain requiring painkillers was slightly shorter in study group compared to control (tab. I). Pain, including chronic inguinal pain syndrome itself, paresthesia, and feeling of foreign body were the most common complication of hernioplasty in all groups. Higher than in control group percentage of fluid collection in study group (4.3% vs. 2.1% and 1.4%) is caused by smaller number of observations. Total number of fluid collections and wound suppurations was higher in suture group (control) compared to FAF (study group). Hernia reoccurrence rate for 18 months was minimal in both groups with minor differences between them.

TABLE I

Comparative evaluation of different inguinal hernioplasties (clinical data)

Indices	Control group (n=71)	Study group (n=23)
Duration of immediate post-operative pain (hrs.)	35.62±3.21	25.39±2.37 $p_1<0.05$
Restoration of basic physical activity (days)	1.80±0.22	1.71±0.35 p >0.05
Restoration of full working capacity (days)	31.12±2.27	30.17±3.62 p >0.05
Postoperative complications:

Notes: p – reliability of differences compared to control group data.

Use of surgical glue reliably improves physical activity and bodily pain indices (tab. II) during postoperative period. Other differences between both groups in other parts of SF-36 questionnaire were less significant including general health perceptions, vitality, and physical role functioning.

TABLE II

Quality of life after hernioplasty according to SF-36 questionnaire in different groups

Indices (points)	Control group (n=39)	II group (n=21)
Physical functioning	85.44±4.09	91.75±5.27 $p_1<0.05$
Bodily pain	84.73±3.91	90.22±5.27 $p_1<0.05$
Vitality	67.85±3.89	68.43±4.85 $p_1>0.05$
Social role functioning	86.41±5.41	86.64±4.18 $p_1>0.05$
Physical role functioning	82.28±4.31	81.46±3.84 $p_1>0.05$
Emotional role functioning	74.43±3.55	76.82±3.59 $p_1>0.05$

Mental health	81.0±3.42	81.91±3.97 $p_1>0.05$

Notes: p – reliability of differences compared to control group data.

DISCUSSION

Tension-free IH repair is a method of choice since last decade. Use of mesh significantly simplified surgery itself, made it faster and safer, leading to very low recurrence rate. However, use of mesh for hernioplasty creates several conditions that may aggravate the outcome of surgery (8, 13). Among them chronic pain syndrome including pain itself, feeling of foreign body, and paresthesia (14) are the most common. Other mesh-associated postoperative complications not typical for surgery using own tissues are seromas, mesh dislocations and deformations.

Possible answer towards these issues is use of glue or anatomical structures for mesh fixation, which may potentially abolish conditions for mentioned above complications (5, 15).

However, suture-free E. Trabuco's technique requires specific graft and does not fully prevent chronic pain syndrome (4, 12). Most of existing comparative studies of use of glue for mesh fixation in groin hernioplasty demonstrate similar or better results compared to classic Lichtenstein technique proving its perspective, though both research bias, and differences of techniques may alleviate the value of obtained results (7).

In this study, we tried to combine both E. Trabuco's anatomical approach and use of other, previously unused glue for mesh fixation. While albumin glue is extensively used in cardiovascular surgery both as adhesive and sealant (9), due to its vulnerability against local fibrinolysis-proteolysis stimulated by both bleeding and surgical trauma including allotransplantation during hernioplasty, there was expectation of weaker mesh fixation compared to other techniques, leading to mesh dislocations, deformities, and higher recurrence rate. This study confirms similar or better results of FAF compared to I. Lichtenstein. Among FAF benefits facilitated chronic pain syndrome is the most important, lead-

ing to faster postoperative recovery and quality of life improvement.

CONCLUSIONS

FAF demonstrated significantly better results compared or comparable results with less acute and chronic postoperative pain and better quality of life than sutures for I. Lichtenstein hernia repair.

No FAF specific complications were demonstrated in this study. Further prospective studies are at need with wider cohort selection, better randomization, and standardization combined with different surgical glues assessment.

CONTRIBUTIONS TO KNOW THE INVOLVEMENT OF CARDIO-VASCULAR DISEASES IN GLAUCOMA ETIOLOGY, STUDIED ON A SAMPLE OF 996 PATIENTS ASSISTED ÎN CLINICO OF OPHTALMOLOGY, "PROF. N. OBLU" EMERGENCY HOSPITAL, IASI (Abstract)**: Material and method:** The authors present the results of clinical and epidemiological research on a sample of 8118 patients assisted in the Ophthalmology Clinic of the Hospital "Prof. Dr. N. Oblu", including 996 (12.1%) with glaucoma, of which 54.1% primary open angle glaucoma (POAG), 22.6%, normal tension glaucoma (NTG), 5.7% primary angle closure-glaucoma (PACG) and 17.6% secondary glaucoma, during 2006-2010. **Results:** For patients with glaucoma authors assessed the prevalence of arterial hypertension (POAG: 33.1%; NTG: 32%; PACG: 8.7%, secondary: 8%), diabetes mellitus (POAG: 19.9%, TNG: 12.9%; PACG: 5.3%, secondary: 5.2%), atherosclerosis (POAG: 10.2%, TNG: 12%; PACG: 5.2%, secondary: 2.9%), vasospasm (POAG: 45 2%, TNG: 47.3%; PACG: 39.3%, secondary: 44.3%). **Key words**: GLAUCOMA, RISK FACTORS, CARDIOVASCULAR, DIABETES MELLITUS, OCULAR VASOSPASM

Deşi au fost identificaţi multipli factori de risc cu potenţial de a induce glaucomul primitiv cu unghi deschis (GPUD), numai unii din aceştia sunt unanim acceptaţi. Dovezile pentru factorii de risc implicaţi în etiopatogenia GPUD au fost obţinute prin studii caz-control, completate cu rezultatele investigaţiilor clinico-epidemiologice. Mulţi dintre factorii de risc pentru GPUD sunt implicaţi în evoluţia bolii şi se referă la cei cu acţiune generală, sistemică şi pentru structurile oculare (1,2).

Cel mai adesea, între factorii de risc sistemici, implicaţi în etiopatogenia glaucomului, se includ: diabetul zaharat, tensiunea arterială (hiper sau hipo), migrena, demenţa senilă Alzheimer, bolile endocrine, apneea de somn, infecţiile şi bolile autoimune (3,4,5,6).

MATERIAL ŞI METODE

Studiul retroprospectiv a inclus 8118 de pacienţi, asistaţi în Clinica a II-a Oftalmologie, Spitalul Clinic "Prof. dr. N. Oblu" Iaşi, în perioada 2006-2010. În baza examenului clinic general şi oftalmologic, pacienţii au fost împărţiţi în două loturi: lotul de cazuri, reprezentat de pacienţii diagnosticaţi cu glaucom (orice formă clinică) şi lotul martor format din cei internaţi pentru diverse patologii oculare. Au fost excluse internările multiple în cazul lotului cu patologie generală (lot

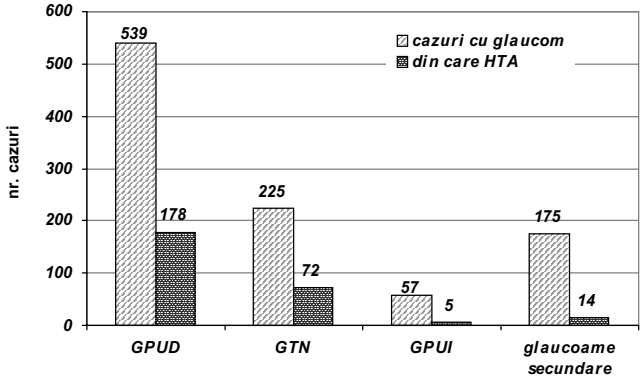

Fig. 1. Distribuţia valorilor de prevalenţă a cazurilor cu HTA în diverse subgrupuri ale pacienţilor cu glaucom, luaţi în studiu

martor), iar pentru lotul de cazuri (996 pacienţi cu glaucom) s-a urmărit evoluţia diferitelor patologii asociate, precum şi identificarea factorilor de risc generali şi oculari asociaţi. Datele evaluate şi incluse într-o fişă clinico-epidemiologică au fost prelucrate şi interpretate statistico-matematic.

REZULTATE ŞI DISCUŢII

1. Tensiunea arterială.

În perioada 2006-2010, din cei 8118 pacienţi cu internări multiple, 996 (12,1%) cazuri s-au prezentat cu glaucom şi au fost evaluaţi, la intervale regulate, atât clinic general, pentru a evidenţia afecţiunile asociate, cât şi oftalmologic. S-a cuantificat implicarea unor afecţiuni cardiovasculare ca factor de risc atât la prima internare cât şi ulterior. Grupul martor a fost format din restul pacienţilor internaţi în Clinica a II-a Oftalmologie, în perioada menţionată, pentru orice patologie oculară, alta decât glaucomul. Au fost excluşi din studiu pacienţii asistaţi în ambulatoriu, în principal datorită imposibilităţii urmăririi evoluţiei afecţiunilor cardiovasculare şi a factorilor de risc implicaţi. Date acumulate au fost incluse într-o fişă de observaţie oftalmologică, pe baza căreia s-a realizat cuantificarea retrospectivă a afecţiunilor cardiovasculare asociate, precum şi a factorilor de risc implicaţi atât în etiopatogenia comorbidităţilor, cât şi în apariţia şi progresia glaucomului (tensiune arterială, colesterol, fumat, diabet zaharat, vasospasm).

În grupul pacienţilor cu altă patologie decât cea glaucomatoasă, hipertensiunea arterială (HTA) a fost înregistrată la 571 (8%) cazuri, care au beneficiat de asistenţă în serviciile de medicină internă.

În relaţie cu forma clinică, pacienţii cu glaucom au fost împărţiţi în subgrupuri, incluzând : GPUD, glaucom cu tensiune normală (GTN), glaucom primitiv cu unghi închis (GPUI) şi forme secundare. Dintre pacienţii cu glaucom, 539 (54,1%) au prezentat GPUD, 225 (22,6%) GTN, 57 (5,7%) GPUI şi 175 (17,6%) cazuri de glaucom secundar.

În grupul cu glaucom, incidenţa HTA a fost de 269 (27,0%), adică de 3,6 ori mai mare decât cea din grupul martor (8,0%). În subgrupuri, s-a remarcat o pondere mai mare a pacienţilor cu HTA : 78 (33,0%) în cazul pacienţilor cu GPUD şi cu GTN. În subgrupurile cu GPUI şi în cel al glaucoamelor secundare, diferenţa incidenţei cazurilor cu HTA a fost nesemnificativă ($p > 0,05$), faţă de martori (GPUI - 8,7% şi glaucom secundar – 8,0%). A rezultat o preponderenţă a cazurilor cu HTA la grupurile cu GPUD şi GTN, fiind cunoscut faptul că factorul vascular poate fi implicat în patogenia creşterii presiunii intraoculare (PIO) (fig. 1).

Este luată în discuţie implicarea modificărilor microvasculare la nivelul capului

nervului optic în apariţia manifestărilor glaucomatoase de la acest nivel. Se ştie că sursele pentru circulaţia prelaminară şi laminară derivă din arterele coroidiene peripapilare şi din arterele ciliare posterioare. Fluxul sangvin poate fi compromis în glaucom prin următoarele mecanisme: afectarea selectivă a vascularizaţiei de la acest nivel, cu o pierdere egală a celulelor ganglionare şi a reţelei capilare, iar bolile microvasculare de tipul diabetului zaharat (DZ), favorizează, în mod semnificativ, instalarea GPUD (7, 8). În toate aceste circumstanţei, autoreglarea fluxului sangvin la nivelului capului nervului optic este perturbată în GPUD.

Studiul Rotterdam (5) a evidenţiat o asociere între o presiune sistolică ridicată şi GPUD, dar nu şi pentru GTN. În lotul studiat de noi, s-a observat o asociere aproximativ egală, atât pentru GPUD, cât şi pentru GTN, iar în relaţie cu aspectul papilei nervului optic în lotul studiat, în tipul senil sclerotic s-a remarcat o asociere semnificativ mai mare a cazurilor de HTA cu apariţia manifestărilor caracteristice pentru glaucom.

În lotul studiat, s-a evidenţiat o preponderenţă a HTA la pacienţii cu tipul senil sclerotic al papilei, pentru ca celelalte grupuri să înregistreze o incidenţă mai scăzută a comorbidităţii cardiovasculare (tab. I).

Unele cercetări (3) au arătat importanţa scăderilor episodice ale TA în glaucom, în special în GTN. Hipotensiunea arterială (hTA) nocturnă este implicată, de asemenea, în patogenia neuropatiei optice ischemice anterioare, legată de prezenţa GPUD şi a GTN, precum şi a progresiei acestora. Pe lotul studiat, incidenţa cazurilor cu hTA a evidenţiat o creştere moderată în grupul cu GTN, asociată posibil şi cu o hTA nocturnă, dificil de evaluat în absenţa unei supravegheri Holter, pentru 24 de ore.

Dintre pacienţii internaţi în Clinica a II-a Oftalmologie, 285 (4%) din grupul celor cu altă patologie decât glaucomul, prezentau hTA, iar la pacienţii cu glaucom, hTA sistemică s-a înregistrat la 9,9% din cazuri.

În relaţie cu forma clinică a glaucomului, se poate vedea o asociere mai frecventă a hTA la pacienţii cu GPUD şi GTN (tab. II).

Hipotensiunea arterială poate determina neuropatie optică glaucomatoasă la unii pacienţi, iar cei cu GTN care riscă această

complicaţie, tind să aibă o scădere mai mare a TA. Până la elucidarea implicării modificărilor TA la toţi pacienţii cu glaucom se consideră necesară măsurarea TA la una din consultaţiile oftalmologice, fără urmărirea Holter pe 24 ore, urmată de un consult cardiologic, care să asigure o terapie corectă.

2. Diabetul zaharat (DZ).

Valorile de prevalenţă ale GPUD sunt mai ridicate la bolnavii cu DZ, în unele studii (6, 7) dovedind prezenţa PIO uşor crescută, cu o prevalenţă mai mare a hipertensiunii oculare şi a glaucomului.

În studiul nostru, în grupul cu altă patologie decât glaucomul, au fost înregistrate 357 (5%) cazuri cu DZ. Din cei 996 de pacienţi cu glaucom, 148 (14,9%) aveau ca patologie asociată DZ. Această asociere ar putea fi explicată şi prin vârsta mai înaintată în grupul cu glaucom, prezenţa HTA, a aterosclerozei şi a altor patologii care determină afectare microvasculară.

Dintre cei 148 pacienţi cu glaucom asociat cu DZ, 82 (55,4%) prezentau şi, iar prevalenţa crescută a DZ în grupul pacienţilor glaucomatoşi arată că acesta este un factor de risc, deşi nu are o prezenţă constantă la pacienţii cu glaucom. S-a constatat o asociere mai frecventă a DZ la subgrupul cu GPUD şi cel cu GTN (tab. III).

Bolnavii cu GPUD par a fi mai receptivi la DZ, fără semnificaţie statistică ($p > 0,05$), deoarece sunt implicaţi ca factori de risc vârsta înaintată şi prezenţa unor comorbidităţi.

Diabetul, prin modificările microvasculare induse, poate determina afectarea autoreglării fluxului sangvin ocular, cu perturbări la nivelul porţiunii anterioare şi a capului nervului optic, care duc la apariţia neuropatiei optice glaucomatoase. De asemenea, DZ compromite funcţiile celulelor gliale şi ale neuronilor, precum şi a metabolismului retinian, care pot duce la o receptivitate crescută a celulelor ganglionare retiniene la variaţiile presionale (7). O afectare prelungită a retinei şi nervului optic prin factori vasculari, gliali şi neuronali poate fi asociată cu un risc mai mare de GPUD. Studiile lui Leske et al. (8) arată un rol potenţial al DZ în patogenia GPUD, pe când alte studii populaţionale (3) nu au evidenţiat o asociere semnificativă.

3. Ateroscleroza (ATS)

În clinica a II-a Oftalmologie, au fost internaţi 216 pacienţi cu ATS, incluşi în grupul celor care au înregistrat o altă patologie

TABELUL V

Asocierea unor aspecte ale vasospasmului subgrupurile cu glaucom, incluzând 7122 pacienţi

Tipul glaucomului	Nr. total cazuri	Extremităţi reci		Migrenă		Vasospasm	
		Nr.	%*	Nr.	%*	Nr.	%*
GPUD	511	165	32,3	115	22,5	231	45,2
GTN	298	95	31,8	62	20,8	141	47,3
GPUI	28	12	42,8	5	17,8	11	39,3
G secundar	79	32	40,5	12	15,2	35	44,3
Total cumulativ	916	304	31,2	194	21,2	418	45,6

* pentru valorile mai mici de 10, proporţiile sunt orientative

decât cea glaucomatoasă. În lotul de 996 pacienţi cu glaucom, prevalenţa celor cu ATS a fost moderat crescută (9%), pentru ca pacienţii cu GPUD şi cei cu GTN să înregistreze o prezenţă mai mare a ATS (10%, respectiv 27%) (tab. IV).

Ischemia cardiacă, angina paectorală şi infarctul miocardic au fost asociate, în variate proporţii, diferitelor forme de glaucom, deşi studiul prospectiv Rotterdam (5) şi alte cercetări nu au identificat o legătură semnificativă între ATS şi glaucom ($p > 0,05$). Hayreh (9) menţionează că serotonina, biomarker specific eliberat în timpul agregării plachetare la nivelul plăcii ateromatoase, la maimuţele cu ATS, produce vasospasmul arterei centrale a retinei şi pe arterele ciliare scurte posterioare, dar nici un studiu nu a permis o vizualizare directă a circulaţiei sangvine oculare la om, pentru a identifica modificările vasculare ale pacienţilor cu GPUD (1,2,7).

Leske et al. (8) se referă la istoria bolilor cardiovasculare ca predictor pentru progresia glaucomului, cu referiri la o incidenţă crescută a ischemiei miocardice silenţioase la pacienţii glaucomatoşi sau la relaţia dintre ischemia cerebrală, infarctul miocardic şi prezenţa glaucomului.

Deşi au fost raportate unele relaţii între factorii de risc aterosclerotici şi GPUD, influenţa directă a aterosclerozei în progresia glaucomului nu este pe deplin determinată.

4. Vasospasmul este o contracţie a vaselor sangvine persistentă, exagerată, rezultând o scădere a lumenului vascular şi a fluxului sangvin. Datele din fişele de observaţie medicală, pentru lotul în studiu, au evidenţiat prezenţa extremităţilor reci şi a migrenei, iar vasospasmul a fost relevat prin ecografia arterei carotide.

Prezenţa migrenei s-a înregistrat cu o prevalenţă de 22,5% la pacienţii cu GPUD şi 20,8% la cei cu GTN. Boala vasospastică fiind mai frecventă la femei la care este recunoscută asocierea, îndeosebi, cu GTN, iar terapia cu blocanţi de calciu poate ameliora hemodinamica retrobulbară (tab. V).

CONCLUZII

Glaucomul este o boală cu manifestări variate şi cu o varianţă mare în evoluţie. Sunt mulţi pacienţi a căror evoluţie este staţionară sau foarte lentă printr-o scădere a PIO. Sunt alţi pacienţi însă cu o reducere identică a PIO care au o progresie a bolii. Sunt factori de risc acceptaţi cum ar fi vârsta înaintată, miopia şi istoricul familial de glaucom. Studiile asupra factorilor vasculari sunt contradictorii, probabil datorită faptului că la doar o proporţie din pacienţii cu glaucom aceştia joacă un rol semnificativ. Este important de a identifica subgrupuri pentru a permite clinicianului o predicţie mai bună a incidenţei şi evoluţiei glaucomului. Aspectele papilei nervului optic este un concept bine definit în practică. Aceste aspecte, alături de forma clinică se pot corela, mecanismele patogenice putând fi similare.

Hipertensiunea arterială este un factor de risc probabil, numeroasele studii nu o-

feră însă o evidenţă clară a implicării HTA. Tensiunea arterială sistolică şi diastolică sunt cercetate independent, cea mai mare valoare etiopatogenică având în momentul de faţă tensiunea arterială diastolică. În lucrarea de faţă am observat o prevalenţă mai mare a hipertensiunii la pacienţii glaucomatoşi, mai evidentă la pacienţii cu glaucom cu unghi deschis şi la cei cu tensiune normală.

În funcţie de asocierile patologice, am observat că la anumite subtipuri ale papilei, recunoscute pentru asocierile cu alte boli cardiovasculare, proporţia pacienţilor cu hipertensiune arterială sistemică este mai mare. Aceasta s-a întâmplat în cazul pacienţilor cu aspect senil sclerotic şi la cei cu lărgire concentrică. Evidenţierea acestor tipuri poate duce la o acţiune mai bună atât asupra evoluţiei glaucomului cât şi a patologiei cardiovasculare asociate.

Modificările microvasculare au fost şi ele implicate în etiopatogenia glaucomului, diabetul zaharat fiind o patologie importantă asociată. Studiul nostru arată o prevalenţă mai mare a diabetului între pacienţii cu glaucom, literatura însă are numeroase studii contradictorii.

În studiul de faţă se vede o preponderenţă a vasospasmului la GTN, dar şi pacienţii cu GPUD au o incidenţă mai mare a manifestărilor periferice ale vasospasmului. Toate manifestările periferice (extremităţi reci), migrena conduc la ideea de scădere a fluxului sanguin în anumite teritorii prin acest mecanism. O evaluare mai bună a patologiei asociate poate conduce la o terapie adecvată, cunoscându-se unele studii care au testat diverse medicaţii (blocanţi ai canalelor de calciu).

În cazul subgrupurilor de glaucom cu unghi închis şi a celor secundare se observă o asemănare cu grupul martor, ştiindu-se mecanismele patogenice diferite. În unele cazuri se observă o incidenţă chiar mai scăzută a unor afecţiuni, probabil datorită cazurilor mai puţine, dar şi datorită vârstei care pentru glaucoamele secundare este mai mică, bolile cardiovasculare apărând la o vârstă mai înaintată.

MANAGEMENT OF MALIGNANT THYROGLOSSAL DUCT CYSTS, A RARE CLINICAL ENTITY IN CERVICAL TUMOR PATHOLOGY (Abstract): Thyroglossal duct cyst is a congenital malformation that occurs at cervical level following an embryonic developmental defect**.** The authors undertook a retrospective study on 143 patients diagnosed with malignant thyroglossal duct cyst in the ENT Clinic of "Sf. Spiridon" County Clinical Emergency Hospital Iasi, between 1992 and 2016 and only 2 cases came out as malignant thyroid gland cyst. This confirms the rarity of this type of lesion, consistent with the data presented in the literature. We present the case of a 51-year-old male case, hospitalized in the ENT Clinic of "Sf. Spiridon" County Clinical Emergency Hospital Iasi, treated by surgical excision of the thyroid gland cyst, performed by using the Sistrunk method. The post-operative histopathological examination of the thyroid gland cyst detected the malignancy. **Conclusions:** The oncology committee of the hospital decided to complete the therapeutic protocol by total thyroidectomy, bilateral neck dissection, radioiodine administration, followed by thyroid hormone replacement. Regular follow-up showed a favorable outcome without complications and no tumoral recurrence at 5 years. **Keywords**: THYROGLOSSAL MALIGNANT DUCT CYST, HISTOPATHOLOGY, RADIOLOGY, SURGERY, ONCOLOGICAL TREATMENT.

INTRODUCTION

Thyroglossal duct cyst is a congenital malformation that occurs at cervical level following an embryonic developmental defect. The thyroid gland developed at the foramen cecum level migrates to the lower third cervical level. The existing tract normally closes after birth. The persistence of this tract can generate the thyroid gland cyst, located between the base of the tongue and the thyroid, with an internal structure of respiratory epithelium and possible thyroid follicles at the external wall of the cyst. The formation is located in the antero-medial cervical section, below the hyoid bone and more rarely the left. It is initially asymptomatic and becomes manifest after an inflammatory episode (1, 2, 3).

In evolution, a fistula can develop, most frequently externally and rarely internally in the pharynx, due to infection. Rarely, the thyroid follicles can undergo malignant transformation. This malignant degeneration most commonly occurs as a thyroid papillary carcinoma developed from the cyst wall.

Differential diagnosis should exclude ectopic thyroid, adenopathy, dermoid cyst, Schwannoma and cystic lymphangiomas (4, 5). In case of thyroid gland cyst malignan-

cy, the accepted therapeutic protocol, that is also cited in the literature, is the complete excision of the thyroid gland and cervical lymph nodes, with post-surgical radioiodine administration followed by thyroid hormone replacement (6, 7).

Between 1992 and 2016, in the ENT Department of "Sf. Spiridon" Hospital from Iasi, Romania, 143 patients were diagnosed with thyroglossal duct cysts, 15 developed thyroglossal duct fistulas, out of which 2 cases were histopathological diagnosed as thyroglossal malignant duct cyst.

Thyroglossal duct cysts and fistulae predominates in the third and fourth decade of life (93 patients), respective 45 patients were female, and 98 patients were male.

The positive diagnosis was based on physical examination combined with cervical echography, scintigraphy, histopathological exam and CT scan for some cases. Patients with thyroglossal duct cysts had a prior asymptomatic mobile neck mass, which gradually expanded, located in the midline or left lateral part of the neck, usually under the hyoid bone. Some thyroglossal duct cysts develop infectious processes and a cutaneous fistula might appear.

All surgeries were performed under general anesthesia. Because the embryological development of the hyoid bone is closely linked to thyroglossal duct cysts, the middle portion of the hyoid bone was excised with the cyst (Sistrunk procedure). In case of malignant cysts, the protocol of the oncologic committee was applied. In five patients who presented fistulae, methylene blue was injected to ease the dissection of the thyroglossal duct cysts.

CASE REPORT

We present the case of a 51-year-old male case hospitalized in the ENT Clinic of "Sf. Spiridon" County Clinical Emergency Hospital Iasi for a cervical mass located below the hypoid bone, which occurred and was observed 2 months ago before being hospitalized, after one episode of upper respiratory tract viral infection. The ENT clinical examination revealed an elastic mass under the hyoid bone, mobile with swallowing.

Cervical echography associated with an endocrinological examination detected a well-defined cystic mass under the hyoid bone stretching to the anterior border of the thyroid cartilage with a normal appearance and topography of the thyroid gland (fig.1).

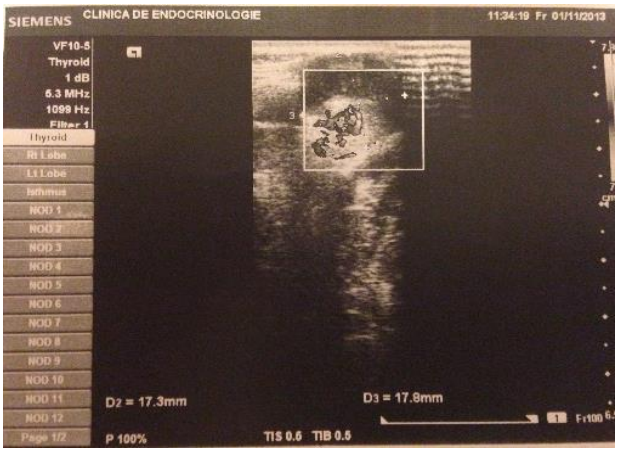

Fig. 1. Echographic image of the cervical mass

The dosage of thyroid hormones was within normal range.

The elected treatment was surgery under general anesthesia by external cervical approach. We performed the dissection of the mass which was adherent to the external perichondrium of the thyroid cartilage, the cranial part being adherent to the hyoid bone, having a tract to the base of the tongue. The whole cyst together with the body of the hyoid bone was excised, ligating the duct above the level of the hyoid bone, using the Sistrunk method (fig. 2-5). The histopathological result showed a cyst wall made up of fibrous tissue with moderate chronic inflammatory microhemorrhage infiltration and a cholesterol deposit, somewhere tapped by a squamous epithelium. Aspects of thyroid papillary carcinoma developed on the thyroid follicles where identified in the wall of the cyst. The examined sections identify adipose tissue and striated muscles with no tumor infiltration and bone fragments without tumor infiltration. The histopathological aspect corresponds to a thyroid papillary carcinoma, pT2NxG2 (fig. 6).

Immunohistochemical (IHC): CK19 - positive in malignant tumor cells, HBME-1 - positive in malignant tumor cells.

The histopathological aspects identified and the IHC profile corresponds to a thyroid papillary carcinoma originating in a thyroid gland cyst.

Fig. 3. Dissection of the cyst

Fig. 4. Post excision appearance

Fig. 5. Excised specimen (cyst + hyoid bone)

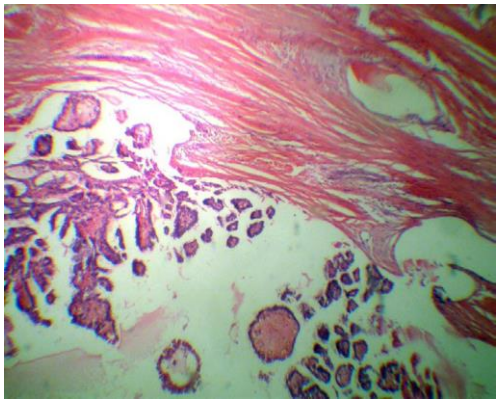

Fig. 6. Histopathological image – thyroid papillary carcinoma

Due to the malignant transformation of the thyroid gland cyst, it required the completion of the therapeutic protocol by performing second surgery for excision of the thyroid gland (total thyroidectomy), followed by application of radiotherapy according to a protocol conducted by the oncological committee.

The postoperative outcome was favorable, with follow-up performed at 1 month, 3 months, 6 months, one year and then annually up to 5 years, without tumor recurrence but requiring thyroid hormone replacement.

DISCUSSION

Thyroid gland cyst, frequent in young adults, is most commonly manifested by a respiratory infection that causes cyst superinfection with increased volume and possible appearance of a fistula.

The need for differential diagnosis to exclude other cervical swelling and thyroid gland pathology is imperative. For this purpose, radiological paraclinical examinations are performed and the patient is endocrinologically examined preoperatively (2).

Endocrinological evaluation, as well as the dynamic outcomes of hormone replacement by administration of Eutirox showed an optimal hormonal substitution level with clinical development in normal parameters that allowed normal social reinsertion of the patient.

The particularity of this case was the malignant transformation of the thyroid gland cyst, the second case encountered in our ENT department over the last 25 years, which corresponds to other statistics stated in the medical literature (7, 8).

A multidisciplinary team consisting of ENT surgeons, radiologists, endocrinologists, histopathologists and oncologists was needed in order to offer the best treatment plan for the patient (9, 10, 11).

The rest of the non-malignant thyroglossal duct cyst cases were resolved by using the Sistrunk surgical procedure, without postoperative complications and no relapse of the tumor (12).

CONCLUSIONS

Malignant thyroglossal duct cyst represents a rare complication of a congenital malformation in ENT pathology, diagnosed postoperatively following the histopathological examination.

The oncological therapeutic protocol requires excision of the thyroid gland as a complementary step, if considering the phylogenetic development of thyroid gland and thyroid gland cyst, followed by radioiodine administration and hormone replacement.

The surgical approach by block excision of the cyst and the hyoid bone body, with the ligature at the base of the tongue (Sistrunk procedure), prevents local relapse and prevents loco-regional complications.

The social reinsertion, the prognosis and the evolution of the patient under the conditions of applying a correct oncological protocol was favorable.

THE ROLE OF MATERNAL OMEGA-3 FATTY ACIDS IN METABOLIC DYSFUNCTIONS IN OFFSPRING

A study by Robertson *et al*. analyses the role of maternal diet during gestation and lactation on the development of the offspring's intestinal microbiota. Metabolic dysfunctions in adult life are influenced by the development of the early-life intestinal flora, which, in turn, is dependent on maternal fatty acid status. To prove this, Robertson *et al* used a transgenic model and showed that maternal n-3 polyunsaturated fatty acid production during gestation or lactation has different effects on male offspring compared to female offspring. Thus, maternal production of polyunsaturated fatty acid significantly reduced weight gain in males fed a high-fat diet but had no significant effect in female offspring. This effect on males persisted into adulthood life and was mediated by restructuring of gut microbiota composition. The microbiota in offspring is influenced more by the maternal fatty acid profile during lactation than in utero. The study shows that reduced exposure to maternal n-3 polyunsaturated fatty acid leads to significantly depleted *Bacteroides*, *Akkermansia* and *Epsilonproteobacteria* and higher relative abundance of *Clostridia* (Robertson RC, Kaliannan K, Strain CR, Ross RP, Stanton C, Kang JX. Maternal omega-3 fatty acids regulate offspring obesity through persistent modulation of gut microbiota. *Microbiome* 2018; 6(1): 95. Published 2018 May 24. doi:10.1186/s40168-018-0476-6).

POLYCYSTIC OVARY SYNDROME – GENETIC CONSIDERATIONS (Abstract): The Polycystic Ovarian Syndrome is one of the most frequent of the endocrinopathies, affecting in average 8% of the woman's that are in to reproductive age. It was first described by Chereau and Rokitanski, further associated with the amenorrhea encountered in the Stein and Levanthal syndrome, exposed by the Irving F, Stein and Michael Leventhal, in 1935. In many aspects this is a systemic disease also interfering with the process of reproduction. The studies of the genetic factor implication, by relating with the specialty literature, converging with a series of hypotesys launch over the years, show a poligenic affliction or a combination of the environment with the genetics factors. Due to the fact that this syndrome is the most frequently encountered cause of infertility among women's, with a very complex etiopathogeny, the comprehension of it, is most important, because the Polycystic Ovarian Syndrome is a metabolic long term disorder. The study of the genetic act implications is a name part in prophylaxis of the appearance of this syndrome or its complications. **Key words**: POLYCYSTIC OVARY SYNDROME, GENETICS REVIEW, APOPTOSIS, FOLLICULOGENESIS, Bcl2, ETHYOPATHOGENY

Sindromul ovarelor polichistice (SOPC) este cunoscut ca fiind cea mai frecventă afecţiune a femeilor aflate la vârsta reproductivă.

Acest sindrom a fost descris prima data de Irving F. Stein şi Michel L. Leventhal, ambii ginecologi din Chicago, în anul 1935, asociat frecvent cu anovulaţie, ce include: amenoree, hirsutism şi ovare marite în volum (micropolichistice), obezitate (nemenţionată, deşi apare în 3 din cele 7 cazuri studiate) (1).

Până în 1935 s-au publicat puţine lucrări care tratează aceleaşi vechi subiecte.

În perioada 1945 – 1955 preocupările sunt orientate spre fundamentarea clinică, anatomică şi morfopatologică, iar din 1955 – 1965, lucrările pun în evidenţa aspectul hormonal, datorită posibilităţii dozărilor în urină şi apoi în sânge. Dupa 1965 cercetările hormonale, devin mai precise graţie dozărilor RIA, a prelevării din venele ovariene şi suprarenale, a sintezelor „in vitro" făcute pe fragmente de ovare polichistice cultivate în prezenţa unor precursori hormonali marcaţi.

SOPC fiind în multe aspecte o boală sistemică, interferă nu numai cu reproducerea, diagnosticul şi tratamentul fiind esenţiale pentru pacientă, nu doar pentru restabilirea fertilităţii ci şi pentru prevenirea complicaţiilor sistemice. Studiul etiopatogeniei SOPC arată probabil o afectare poligenică sau o combinaţie a factorilor genetici cu cei de mediu. Chiar dacă implicarea unor sisteme adiacente în dereglările funcţionale ovariene a fost suspectată încă de la începutul „istoriei" acestei afecţiuni, ultimii ani au fost extrem de prolifici în suportul

conceptului patogenic multifactorial.

Lucrarea de faţă prezintă o relatare şi o urmărire a diverselor implicaţii ale factorului genetic în etiopatogenia SOPC.

În literatura de specialitate studiile demonstrează incidenţa crescută a acestui sindrom la rudele de sex feminin ale femeilor afectate. În istoricul familial al pacientelor regăsim diabet zaharat tip II, obezitate, hipertensiune arterială, hipertrigliceridemie (componente ale sindromului X metabolic).

Mulţi autori susţin ipoteza că androgenii crescuţi pot avea ca rezultat expresia unor gene legate de apoptoză şi consecutiv expresia factorilor de creştere şi/sau a receptorilor factorilor de creştere.

SINDROMUL OVARELOR POLICHISTIC – IMPLICAŢII GENETICE ÎN ETIOPATOGENIE

Există mai multe ipoteze majore care caută să explice apariţia sindromului ovarelor polichistice, deşi adesea se pot împleti în realitate.

Studiile relatate în literatura de specialitate arată o răspândire familială, anormalităţile gonadale (atât la femei cât şi la bărbaţi) fiind corelate cu o expresie crescută a EGF şi TGF alfa până la 80% dintr-o familie (2). Tendinţa la alopecie precoce (ce apare în familiile femeilor cu SOPC) a fost descrisă pe linie paterna sau materna, cu o transmitere autosomal dominanta (3).

Sunt o mulţime de ipoteze care încearcă sa puna în evidenţă genele responsabile de apariţia sindromului (4).

Una dintre ipoteze arata ca sinteza crescută de androgeni, care apare în acest sindrom, s-ar datora unui complex citocrom P450 C17 cu activitate crescută a enzimelor steroidogenetice (dehidrogenaze sau enzime din grupul de oxidaze). Citocromul P450 este numele generic atribuit unei clase de enzime oxidative. Termenul de 450 este atribuit datorită absorţiei unui pigment (450) în cursul reducerii. In cursul steroidogenezei sunt implicate următoarele enzime P450 : P450scc, P450c11, P450c17, P450arom. Steroidogeneza pe termen lung necesită transcripţie genetică şi sinteze proteice, în timp ce steroidogeneza pe termen scurt se produce independent de o nouă sinteză de ARN (5) .

Celulele tecale ovariene sunt caracterizate prin activitate steroidogenetică ca răspuns la hormonul luteinizant (LH), cu producere de precursori androgeni, prin activarea genelor responsabile de transcripţia P450scc, P450c17 şi a 3beta- hidroxisteroidogenazei (6). Aromatizarea androgenilor în estrogeni este o acţiune specifică celulelor granuloase ovariene, indusă de hormonul foliculostimulant (FSH) prin activarea genei P450arom.

Ar mai fi o altă ipoteză care consideră că există o deficienţă structurală de fond a ovarelor în aromatază, 17-hidroxilază şi 3--beta-hidroxisteroiddehidrogenază cu o sinteză ovariană scăzută de estrogeni şi o stimulare insuficientă a sintezei de gonadotrofine.

În cazul SOPC, absenţa ovulaţiei este asociată cu oprirea în creştere a foliculilor, la cca 10 mm diametru şi cu o producţie excesivă de androgeni de către celulele tecale ale foliculilor blocaţi. În termenii celor două celule (granuloasă şi tecală), degenerează compartimentul granulos, teaca rămânând să continue secreţia hormonală. Cauza primară (hipersecreţia de LH, de insulină sau o mutaţie a genei codante pentru enzima P450 care clivează lanţul de cholesterol), nu este cunoscută.

Foliculogeneza imperfectă poate fi datorată şi expresiei deficiente a factorului de diferenţiere a creşterii ovocitar (growth differentiation factor-9 - factor de creştere din familia TGFbeta. Inactivarea genei responsabile antrenează blocajul precoce al dezvoltării foliculare (7).

O ipoteza considera atrezia foliculară ca un proces apoptotic posibil în celulele granuloase ale foliculilor atretici, din cauza similarităţii morfologice între acestea şi celulele care suferă apoptoza (8).

Conceptul de moarte programată a celulelor, ca eveniment fiziologic a fost mai întâi analizat în ovar, în reglarea apoptozei având un rol important sistemul Fas (LH interferă cu acesta având efect antiapoptotic) (9).

Apoptoza trece prin etape distincte morfologic. Contrar necrozei sau morţii degenerative a celulelor, apoptoza este un mod controlat netoxic al morţii celulelor.

Ovarul, în timpul vieţii reproductive a femeii, suportă o remodelare extensivă şi există dovezi care sprijină rolul apoptozei ca mecanism de bază pentru menţinerea homeostaziei în ciclul ovarian.

Sunt cel puţin patru căi diferite prin care apoptoza poate afecta ovarul în SOPC :

1. rata crescută a apoptozei foliculilor poate avea ca rezultat atrezia foliculară crescută ;
2. apoptoza crescută a oocitelor poate avea ca rezultat o rată scăzută a ovulaţiei ;
3. apoptoza crescută a celulelor granuloasei foliculare poate exagera hiperandrogenismul, întrucât androgenii nu sunt convertiţi în estrogeni ;
4. atrezia foliculară totuşi, poate fi anormală în SOPC. Chisturile foliculare pot rezulta din atrezia atenuată în care programul normal al morţii celulare foliculare este atenuat (10).

Prelungirea intervalului de viaţă a foliculilor atretici poate duce la formarea de chisturi.

Genele reglează apoptoza, fie să promoveze, fie să prevină instalarea morţii programate a celulelor. Aceste gene pot fi activate de stimuli externi sau pot fi independente de factorii de mediu.

Foliculogeneza ovariană este caracterizată prin intense procese de proliferare, de diferenţiere celulară a celulelor granuloase în creştere (steroidogeneza) şi de asemenea şi de fenomene de moarte celulară programată în foliculii atretici. Inactivarea unor gene implicate în oricare din aceste procese duce la alterarea funcţiei ovariene. Astfel, inactivarea genei cyclinei D2 (Ccnd2) responsabilă în parte de proliferarea granuloasei, antrenează scăderea importantă a greutăţii ovarelor (11). Este deosebit de importantă observaţia că, în numeroase tumori ovariene, la femeie, au fost identificate niveluri crescute de mARN Ccnd2, care codează cyclina D2 (12).

O situaţie asemănătoare se produce şi prin inhibarea genei antiapoptotice Bcl2 (13). Ovarele cu această genă inhibată prezintă o diminuare cu 30% a numărului de foliculi primordiali (14).

Studiile în care s-a examinat apoptoza mediată de Fas 670 A/G în celulele granuloase şi cardiace umane au demonstrat că această genă joacă un rol important şi în patogeneza bolilor cardiace, asociate frecvent cu sindromul ovarelor polichistice (15).

Apoptoza alterată ar putea să contribuie şi la patogeneza tiroiditei, fie prin lezarea celulară iniţială care duce la răspuns imun, fie prin apoptoza mediată imun a celulelor foliculare tiroidiene care duce la hipotiroidism, un mare număr de femei cu SOPC prezentând o hipofuncţie tiroidiană (16). Hormonii tiroidieni, metabolismul lipidic şi nivelurile de insulină regleaza nivelurile serice ale leptinei – proteina obezităţii – care se găseşte în celulele granuloase prelevate din foliculii preovulatori şi acţionează pe căi autocrine şi paracrine, (implicată în reglarea greutăţii corporale, fiind cel mai bun marker pentru grăsimea totală din organism (17,18).

Mecanismul prin care hiperinsulinemia se asociază cu hiperandrogenismul este explicat printr-un defect în fosforilarea serinei lanţului beta al insulinei şi al enzimei P450c17 ovariană şi suprarenaliană. Fosforilarea serinei creşte, iar defosforilarea serinei descreşte activitatea enzimei 17, 20 liaza, implicată în producţia androgenilor (19,20). Astfel, fosforilarea serinei este un “buton de închidere (off)” pentru mecanismul de

transport al glucozei şi "buton de deschidere (on)" pentru producţia de androgeni.

Astfel, aceeaşi manifestare clinică poate apare în mai multe circumstanţe, printr-un defect al receptorilor de insulină sau afectare post receptor a funcţiei acestuia, având drept rezultat comun, fosforilarea crescută a insulinei (21).

Un procent de 40-50% dintre femeile cu SOPC şi obezitate vor dezvolta diabet zaharat sau toleranţă scăzută la glucoză până la vârsta de 30 ani. Hipertrigliceridemia, hipercolesterolemia, nivele scăzute de HDL sunt factori majori de risc pentru boala coronariană, risc ce se amplifică pe măsură ce pacientele înaintează în vârstă. Sunt studii care arată concentraţii crescute în ser a IMA (ischaemia-modified albumin) la paciente cu SOPC, un marker ischemic nou în boala coronariană (22). Rezistenţa la insulină determină consecinţe pe termen lung cu apariţia diabetului zaharat, a tulburărilor cardiovasculare, cât şi a celor de fibrinoliză, a hiperuricemiei a relaţiei cu inflamaţia sistemică care sunt dezbătute în continuare. SOPC prin asocierea cu obezitate şi insulinorezistenţă este un factor de risc pentru apariţia steatozei hepatice nonalcoolice (NASH) care duce la ciroză, hipertensiune portală, insuficienţă hepatică şi carcinom hepatocelular (complicaţii pe termen lung). În serul pacientelor cu acest sindrom s-au detectat nivele crescute ale capsazei 3, marker apoptotic pentru NASH (23).

SOPC şi diabetul zaharat tip II sunt forme clinice ale aceleiaşi rezistenţă la insulină cu aspecte fenotipice diferite funcţie de localizarea ovariană sau pancreatică a unui defect genetic. Un defect ar putea fi alterarea proprietăţilor stoichiometrice ale complexului proteinkinază A (PKA) – lipază hormono-senzitivă (HSL), ceea ce duce la o lipoliză crescută indusă în celulele adipoase viscerale (defect primar de lipoliză).

Având în vedere asocierea SOPC cu un risc crescut de diabet zaharat tip II, s-a propus studierea unor defecte genetice comune cu acesta (24). Enzima Calpain-10 este o cistein protează care participă la secreţia şi acţiunea insulinei (25). Variaţii ale genei care codifică Calpain-10 se asociază cu diabetul zaharat tip II (26).

În literatura de specialitate sunt studii care arată transmiterea autozomal dominantă, incidenţa hirsutismului, a calviţiei premature la barbaţi şi a oligomenoreei fiind de două ori mai frecvente decât în populaţia generală, dar cu manifestare fenotipică variabilă (27,28). De asemenea legăturile directe între hiperandrogenie şi hiperinsulinism sugerează că efectul stimulator al insulinei asupra producţiei ovariene de androgeni este influenţată de o predispoziţie sau susceptibilitate genetică. In familiile femeilor cu anovulaţie, hiperandrogenism şi ovare polichistice se constată o incidenţă crescută a hiperinsulinismului la femei şi a calviţiei premature la bărbaţi. Studiile genetice, aflate încă la început, implică în această afectare locusurile genetice pentru insulină şi pentru P450scc, nu şi pentru P450c17alfa. Este necesară investigarea familială în acest sens şi avertizarea familiilor cu SOPC privind predispoziţia pentru aceste afecţiuni.

Se consideră că interacţiunea unei anormalităţi a insulinei cu o tulburare a sintezei ovariene de androgeni, poate explica modificările din sindrom. S-a descris o asociere a acestui sindrom şi un genotip anume VNTR (variable number of tandem repeats) de la nivelul cromozomului 11p15,5 implicat în expresia insulinei, astfel, o alterare moştenită în secreţia insulinei ar putea fi implicată în etiopatogenia SOPC. Pornind de la citP450c17alfa, implicat în mai multe lanţuri patogenice, s-a încercat identificarea unui posibil defect asociat, însă studiile au exclus existenţa unui defect la nivelul CYP 17. Se pare însă că un defect la nivelul CYP11A care codifică P450scc, ar constitui,

alături de polimorfismul VNTR, bazele genetice ale SOPC (29,30). De asemenea, în cazul obezităţii, a cărei prevalenţă în SOPC a fost estimată la 50%, se estimează un defect genetic de 25%, chiar de 30-35% în cazul obezităţii troncoabdominale (31). Puternica asociere familială sugerează existenţa unui factor genetic în determinismul sindromului sau măcar al unor componente ale sale, dar heterogenitatea manifestărilor clinice şi biochimice pledează pentru o asociere multigenică.

Prima semnalare a asocierii între intoleranţa la glucoză şi hiperandrogenie a fost făcută de Archand şi Thiers în 1921, referitor la femeile diabetice cu "barbă" (32). Astăzi, relaţia între rezistenţa la insulină şi sindromul ovarului polichistic este unanim recunoscută.
